1.0 EXECUTIVE SUMMARY

RESPEC Company LLC ("RESPEC") has prepared this technical report summary on the Sleeper gold-silver project at the request of Paramount Gold Nevada Corp. ("Paramount"), a United States ("U.S.") listed company (PZG: NYSE American) based in Winnemucca, Nevada. The Sleeper gold-silver project is located in Humboldt County, Nevada, and was the site of historical open pit mining from 1986 to 1996 when a total of approximately 1.66 million ounces of gold and 2.3 million ounces of silver were produced. This report provides a technical summary and a current estimate of gold and silver mineral resources for the project under the U.S. Securities and Exchange Commission ("SEC") Regulation S-K.

1.1 PROPERTY DESCRIPTION AND OWNERSHIP

The Sleeper property consists of 2,474 unpatented Federal lode mining claims covering approximately 18,177 hectares in parts of Sections 3 to 11, 14 to 23 and 26 to 36, inclusive, in Township 40 North, Range 35 East, Sections 1 to 12 15 to 21 and 29-33, Township 39 North, Range 35 East, Sections 1, 2, 11 and 12, Township 38 North, Range 34 East, Sections 2, 4, 8, 16 and 28, Township 37 North, Range 35 East, Sections 24 and 36, Township 37 North, Range 34 East, and Section 2, Township 36 North, Range 34 East, inclusive, Mount Diablo Base and Meridian, Humboldt County, Nevada. The main historical mine workings are centered at Lat: 41° 20' N, Long: 118° 03' W.

Paramount and two 100%-owned subsidiaries, Sleeper Mining LLC and New Sleeper LLC., own 100% of the mining claims comprising the Sleeper property. Ownership of the unpatented mining claims is in the name of the holder (locator), subject to the overall title of the United States of America. Under the Mining Law of 1872, the locator has the right to explore, develop, and mine minerals on unpatented mining claims without payments of production royalties to the U.S. government. The 2,474 unpatented lode claims include rights to all locatable subsurface minerals. Currently, annual claim-maintenance fees of $165 per claim are the only federal payments related to unpatented mining claims. As of the effective date of this report, these fees have been paid in full to September 1, 2023.

1.2 GEOLOGY AND MINERALIZATION

The Sleeper gold-silver deposit was discovered by AMAX Gold Inc. ("AMAX") in late 1984. The Sleeper mine was constructed by AMAX in the mid-1980s as an open pit operation that produced approximately 1.658 million ounces of gold from 1986 to the end of production in 1996. Silver production totaled approximately 2.3 million ounces.

The deposit is located on the western flank of the Slumbering Hills and is largely covered by Quaternary gravels, alluvium, colluvium, and a surficial sequence of eolian sand. Gold-silver mineralization is situated nearly entirely in the hanging wall of a major, northwest-trending, west-dipping range-bounding normal fault that separates Mesozoic metasedimentary rocks of the Auld Lang Syne Group in the footwall from middle Miocene lavas, flow breccia, and lesser

210 SOUTH ROCK BOULEVARD
RENO, NV 89502
775.856.5700

epiclastic and tuffaceous rocks in the hanging wall. The principal host rocks for the deposit are a sequence of middle Miocene basalt and rhyolite lavas, domes, and small-volume tuffs.

Prior to mining, the Sleeper deposit consisted of four spatially overlapping types of gold-silver mineralization: a) banded quartz-adularia-electrum-(sericite) veins; b) silica-pyrite-marcasite cemented breccias; c) quartz-pyrite-marcasite stockworks; and d) alluvial gold-silver placers in Pliocene gravels.

The Sleeper veins generally dip to the west at moderate to high angles, but some secondary hanging-wall offshoots of the principal vein structures dip steeply to the east. Significant zones of mineralization at Sleeper extended for about 1,500 meters along strike, about 600 meters of width, and from near the pre-mining surface to depths of more than 610 meters. At least eleven veins with bonanza grades were mined historically. The Sleeper Main vein produced more than 0.5 Moz of gold from a single bonanza ore shoot, which had a strike length of 850 meters and width ranging from 0.3 to 4.6 meters. Most discrete bonanza zones consisted of a series of sheeted chalcedonic quartz veins distributed over cumulative widths of 10 to 25 meters. Individual veins ranged in thickness from a few centimeters to locally 5 meters.

The post-mining Sleeper deposit is predominantly characterized by extensive, low-grade stockwork mineralization hosted within the Sleeper rhyolite and underlying basalts. The stockwork mineralization has numerous, randomly oriented quartz-pyrite-marcasite veinlets peripheral to mid- to high- grade veins and breccias. The mid-grade mineralization consists of clast-supported breccias and narrow veins which extend down-dip from previously mined high-grade veins. These mid-grade narrow veins typically assay between 3 and 34 g Au/t, whereas the stockwork assays usually result in grades less than 3 g Au/t.

The West Wood area to the southwest of the Sleeper pit contains high-grade mineralization within a hydrothermal breccia body associated with faults and a felsic porphyritic intrusive. This zone likely represents a down-faulted block that was continuous or parallel to the West vein mined in the pit. The West Wood breccia is highly silicified with abundant sulfides, but localized veins within the breccia can exceed 100 g Au/t.

1.3 STATUS OF EXPLORATION, DEVELOPMENT AND OPERATIONS

Paramount is not engaged in development or operations at the Sleeper project as of the effective date of this report. Exploration conducted by Paramount from 2010 through 2013, and in 2021, is summarized in Section 7.0.

1.4 METALLURGICAL TESTING AND MINERAL PROCESSING

Recovery assumptions used in the Whittle optimization were:

- Alluvium – 72% for gold and 8% for silver;
- Mine Dumps – 72% for gold and 42.5% for silver;
- Facilities Area – 79% for gold and 8% for silver;
- Sleeper Area – 85% for gold and 10% for silver;
- West Wood Area – 72% for gold and 9% for silver;
- Mixed Material – 67.5% for gold and 20% for silver; and
- Biooxidation Heap Leach (sulfide) Material – 73% for gold and 43% for silver

1.5 MINERAL RESOURCE ESTIMATE

Inferred resources, effective June 30, 2022, consist of a total of 215,546,000 tonnes with an average gold grade of 0.349 g Au/t and an average silver grade of 3.53 g Ag/t, for 2,417,000 contained ounces of gold and 24,458,000 contained ounces of silver. The resources are constrained within an optimized pit, reflecting the potential for open pit mining and heap-leach processing of the present Sleeper deposit. The Sleeper resources are comprised of 21% oxidized, 27% mixed, and 52% unoxidized materials. The in-pit resources are reported at cutoffs of 0.137 g Au/t for oxide and mixed material, and 0.251 g Au/t for sulfide material. The cutoff for unoxidized materials reflects the potential for biooxidation prior to leaching.

Table 1-1 Sleeper Total In-Pit Gold and Silver Resources – Inferred

(Metric units)

Cutoff					
g Au/T	K Tonnes	g Au/T	K oz Au	g Ag/T	K oz Ag
Variable	215,546	0.349	2,417	3.53	24,458

(US Units)

Cutoff					
Oz Au/t	K tons	Oz Au/t	K oz Au	Oz Ag/t	K Oz Ag
Variable	237,578	0.0102	2,417	0.103	24,458

Notes:

- The estimate of mineral resources was done by RESPEC in metric tonnes.
- Mineral Resources comprised all model blocks at a 0.137 g Au/t cut-off for Oxide and Mixed within an optimized pit; 0.251 g Au/t for Sulfide within an optimized pit; and 0.137 g Au/t for dumps.
- The average grades of the Inferred Mineral Resources are comprised of the weighted average of Oxide, Mixed, Sulfide, and dumps mineral resources. Alluvium mineralized materials are not included in the mineral resources.
- Mineral Resources within the optimized pit are block-diluted tabulations. Dumps mineral resources are undiluted tabulations.
- Mineral Resources that are not Mineral Reserves do not have demonstrated economic viability.
- Mineral Resources potentially amenable to open pit mining methods are reported using a gold price of US$1,750/oz, a silver price of US$22/oz, a throughput rate of 30,000 tonnes/day, assumed metallurgical recoveries of 72.7% for Au and 28.2% for Ag, mining costs of US$2.00/tonne mined, heap leach processing costs of US$3.08/tonne processed, bio-leach processing costs of US$9.84/tonne processed general and administrative costs of $0.46/tonne processed. Gold and silver commodity prices were selected based on analysis of the three-year running average at the end of August 2022.
- The effective date of the estimate is June 30, 2022.
- Rounding may result in apparent discrepancies between tonnes, grade, and contained metal content.

1.6 CONCLUSIONS AND RECOMMENDATIONS

The current Sleeper mineral resources are principally comprised of the substantial volumes of the lower-grade mineralization that envelops the Sleeper veins both vertically and laterally. This lower-grade envelope is dominated by stockwork mineralization, but moderate- to high-grade mineralization within it includes the down-dip extensions of the mined-out Sleeper high-grade veins as well as other secondary and tertiary structural zones that host hydrothermal breccias of moderate grades. The unmined West Wood occurrence also lies within the low-grade halo mineralization. West Wood is comprised of mid- to high-grade gold mineralization hosted within an easterly dipping, sulfidic hydrothermal breccia that is related to a felsic porphyritic intrusion, and it lies to the southwest of the AMAX pit limits.

While the drill density is sufficient to potentially define resources of high categories, the current resources are classified entirely as Inferred due to the need for further data verification. Much of the historical drilling information that exists only in hard-copy formats has yet to be compiled and evaluated. It is recommended that special attention be given to compiling and fully evaluating the available historical drilling information, including assay methods and QA/QC procedures and results. The Sleeper database includes multiple generations of data accumulated from several companies. While about 10% of the drill holes have undergone verification auditing, further verification is recommended. This includes all drill hole information such as collar surveys, down-the-hole surveys, assays, from-to intervals, etc. Once this validation is completed and depending on the issues that need to be resolved, there may be opportunities to upgrade the classification of portions of the estimated mineral resources at Sleeper.

Following completion of the database audit, an updated estimate of the mineral resources is recommended. If the audit allows for sufficient re-classification of a portion of the resources to Indicated and/or Measured status, a preliminary economic assessment ("PEA") is recommended to assess the preliminary project economics.

If the results of the recommended resource update and recommended PEA are favorable, an infill drill program of approximately 7,600 meters of drilling is recommended. The drilling is proposed to be completed by RC methods. However, RESPEC recommends that core drilling be substituted for a portion of the RC drilling due to the emerging understanding of the importance of narrow high-grade veins and steeply dipping structural controls, and to avoid the demonstrated down-hole contamination that has occurred below the water table. Core drilling would also provide opportunities to collect information regarding geotechnical data, hydrology, metallurgical testing, and validate historical RC drilling. Increased drill density is required in some areas to provide confidence needed to potentially upgrade Inferred resources to Measured and Indicated classifications.

Table 1-2. Cost Estimate for the Recommended Program

Category	Estimated Cost ($)
Data Compilation and Database Verification	$100,000
Preliminary Economic Assessment	$150,000
Infill RC Drilling (7,600 meters at $132/m)	$1,000,000
Metallurgy including biooxidation test work	$250,000
Pre-Feasibility Study	$2,500,000
Total	$4,000,000

2.0 INTRODUCTION

RESPEC Company LLC ("RESPEC") has prepared this technical report summary on the Sleeper gold-silver project at the request of Paramount Gold Nevada Corp. ("Paramount"), a United States ("U.S.") listed company (PZG: NYSE American) based in Winnemucca, Nevada. The Sleeper gold-silver project is located in the Awakening mining district of Humboldt County, Nevada, and was the site of historical open pit mining from 1986 to 1996 when a total of approximately 1.66 million ounces of gold and 2.3 million ounces of silver were produced.

The purpose of this report is to provide a technical summary and an updated, current estimate of gold and silver mineral resources for the project in support of Paramount's regulatory obligations under the U.S. Securities and Exchange Commission ("SEC") and Code of Federal Regulations subpart 229.1300 of Regulation S-K ("S-K 1300"). The Sleeper property is considered a material property under S-K 1300. This technical report summary supersedes the most recent Canadian National Instrument 43-101 ("NI 43-101") technical reports and estimated resources for the Sleeper project prepared for Paramount by Wilson et al. (2015 and 2017) prior to the implementation of S-K 1300.

2.1 SOURCES OF INFORMATION

The scope of this technical report summary included a review of pertinent technical reports and data provided to RESPEC by Paramount relative to the general setting, geology, project history, exploration activities and results, methodology, quality assurance, interpretations, drilling programs, and metallurgy. RESPEC has fully relied on the data and information provided by Paramount for the completion of this report, drawing most significantly on the reports of Wilson et al. (2015) and Wilson et al. (2017), as well as other sources of information cited specifically in portions of this technical report summary and listed in Section 24 References. RESPEC has also utilized information derived from work done by Paramount's predecessor operators of the project, and on observations made by RESPEC geologists during their site visits. RESPEC has reviewed much of the available data and has made judgments about the general reliability of the underlying data. Where deemed either inadequate or unreliable, the data were either eliminated from use or procedures were modified to account for lack of confidence in that specific information. RESPEC has made such investigations as deemed necessary in their professional judgment to be able to reasonably present the conclusions discussed herein.

2.2 PERSONAL INSPECTIONS

RESPEC conducted multiple site visits to the Sleeper project guided by Mr. Glen Van Treek and/or Mr. Michael McGinnis of Paramount on four separate occasions: April 19 and November 18, 2021, and March 2 and May 11, 2022. RESPEC examined the property infrastructure, reviewed representative drill core and RC cuttings, evaluated the status of drill sample pulps stored on site, and measured the coordinates of selected drillhole collar locations. The geology of the Sleeper deposit was reviewed through an examination of drill core from selected drill holes and printouts of Paramount's cross-sections.

2.3 EFFECTIVE DATE

The effective date of the current mineral resources is June 30, 2022, and the effective date of this technical report summary is June 30, 2022. In this report, measurements are generally reported in metric units. Where information was originally reported in Imperial units (U.S. customary units), RESPEC has made the conversions as shown below. Units of measure, and conversion factors used in this report include:

2.4 UNITS OF MEASURE AND FREQUENTLY USED ACRONYMS

Linear Measure		
1 centimeter	= 0.3937 inch	
1 meter	= 3.2808 feet	= 1.0936 yard
1 kilometer	= 0.6214 mile	
Area Measure		
1 hectare	= 2.471 acres	= 0.0039 square mile
Capacity Measure (liquid)		
1 liter	= 0.2642 US gallons	
Weight		
1 tonne (metric)	= 1.1023 short tons	= 2,205 pounds
1 kilogram	= 2.205 pounds	
1 troy ounce (oz)	=31.1034768 grams	

Currency: Unless otherwise indicated, all references to dollars ($) in this report refer to currency of the United States.

Frequently used acronyms and abbreviations are listed in Table 2-1.

Table 2-1. List of Units, Acronyms, and Abbreviations

AA	atomic absorption spectrometry
Ag	silver
Ai	abrasion index
Au	gold
AV	absolute value
BWi	bond ball mill work index
cm	centimeters
CBA	complete bouguer anomaly
core	diamond core-drilling method
CRMs	certified reference material
ºC	degrees centigrade
°F	degrees Fahrenheit

Table 2.1. List of Units, Acronyms, and Abbreviations (continued)

ft	foot or feet
g/t	grams per tonne
g/cm^3	grams per cubic centimeter
g/cc	grams per cubic centimeter
gpm	gallons per minute
hp	horsepower
Hz	Hertz

P_{80}	nominal size at 80 percent
ppm	parts per million
QA/QC	quality assurance and quality control
R or Res	resistivity
RC	reverse-circulation drilling method
Resource Pit	optimized pit shell for the Sleeper Deposit Resources
RPD	relative percent difference
RQD	rock-quality designation
RTK	real-time kinematic
RTP	reduced to the pole
SWIR	short-wave infrared
t	metric tonne or tonnes
T	imperial short ton (2,000lb)
Tph	imperial short ton per hour
UCL	upper control limit
USL	upper specification limit
VD	vertical derivative

3.0 PROPERTY DESCRIPTION AND LOCATION

RESPEC is not an expert with regard to legal, environmental and social matters such as the validity of mining claims and agreements and environmental permitting. RESPEC has relied fully on Paramount for the information in Section 3.1 through Section 3.6 as summarized in Section 25.0.

3.1 PROPERTY LOCATION

The Sleeper property is located in Desert Valley and the adjoining Slumbering Hills in Humboldt County, Nevada, U.S.A. The claims cover parts of Sections 3 to 11, 14 to 23 and 26 to 36, inclusive, in Township 40 North, Range 35 East, Sections 1 to 12 15 to 21 and 29-33, Township 39 North, Range 35 East, Sections 1, 2, 11 and 12, Township 38 North, Range 34 East, Sections 2, 4, 8, 16 and 28, Township 37 North, Range 35 East, Sections 24 and 36, Township 37 North, Range 34 East, and Section 2, Township 36 North, Range 34 East, inclusive, Mount Diablo Base and Meridian, Humboldt County, Nevada, U.S.A. The property location is shown on Figure 3-1. The main historical mine workings are centered at Lat: 41° 20' N, Long: 118° 03' W (Figure 3-2).

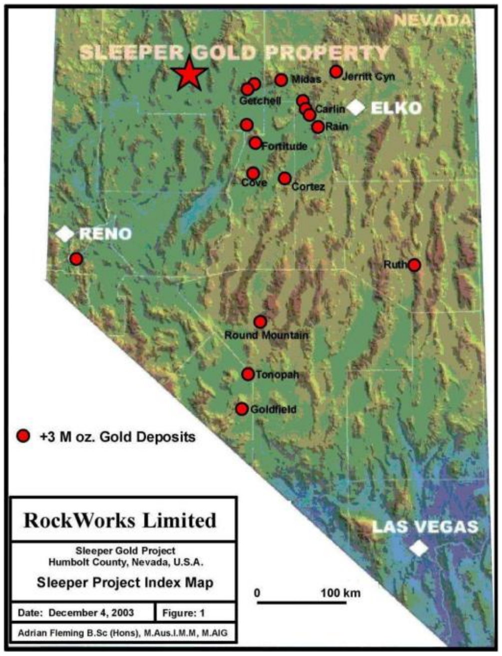

Figure 3-1. Location Map for the Sleeper Property
(from Gustin and Fleming, 2004)

3.2 PROPERTY AREA AND CLAIM TYPES

The Sleeper property () comprises 2,474 unpatented Federal lode mining claims covering approximately 18,177 hectares. This includes 152 unpatented mining claims identified as the RO and SH group of claims, located 5.6 kilometers southwest of the main Sleeper pit, acquired by Paramount on March 31, 2021. Appendix A contains a list of the individual lode claims that comprise the Sleeper property.

Paramount's ownership of the Sleeper project commenced in 2010 when a predecessor company known then as Paramount Gold and Silver acquired X-Cal Resources Ltd. ("X-Cal"), which held portions of the Sleeper property. In 2011, Paramount Gold and Silver acquired ICN's land package in the area south of the Sleeper deposit, and in 2012 Paramount Gold and Silver staked additional claims. In connection with a merger agreement between Paramount Gold and Silver, Coeur Mining, Inc. and Hollywood Merger Sub, Inc., Paramount Gold and Silver spun-off Paramount as a separate, publicly traded company owning 100% of two subsidiaries, Sleeper Mining LLC and New Sleeper LLC., that together with Paramount own 100% of the mining claims comprising the Sleeper property.

3.3 MINERAL RIGHTS

Ownership of the unpatented mining claims is in the name of the holder (locator), subject to the overall title of the United States of America, under the administration of the U.S. Bureau of Land Management ("BLM"). Under the Mining Law of 1872, which governs the location of unpatented mining claims on federal lands, the locator has the right to explore, develop, and mine minerals on unpatented mining claims without payments of production royalties to the U.S. government, and subject to the surface management regulation of the BLM. The 2,474 unpatented lode claims include rights to all locatable subsurface minerals. Currently, annual claim-maintenance fees of $165 per claim are the only federal payments related to unpatented mining claims. As of the effective date of this report, these fees have been paid in full to September 1, 2023. The annual property holding costs, including claim fees and county recording fees total an estimated $437,898 (Table 3-1).

Surface rights sufficient to explore, develop, and mine minerals on the unpatented mining claims are inherent to the claims as long as the claims are maintained in good standing. The surface rights are subject to all applicable state and federal environmental regulations.

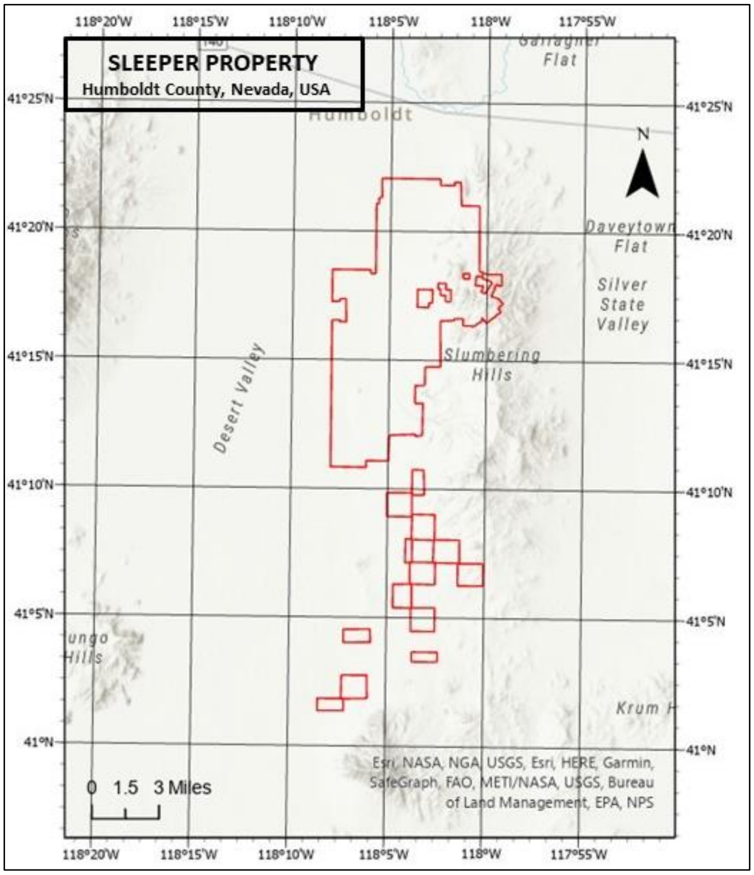

Figure 3-2: Sleeper Property Location Map
(from Paramount, 2022; red lines show outlines of Paramount claim blocks and third-party inliers.)

Table 3-1. Summary of Annual Property Holding Costs

Type	Annual Claim Fees	Annual County Recording Fees	Total Annual Costs
Unpatented Lode Claims	$408,210	$29,688	$437,898

3.4 SIGNIFICANT ENCUMBRANCES AND PERMITTING

The Sleeper property is owned 100% by Paramount with no significant encumbrances or agreements such as leases, options, or purchase payments known to RESPEC. The project is currently operated as an advanced exploration project. Key BLM and State permits associated with these activities and in place as of the effective date of this report include:

Exploration Reclamation Permit #0219

Exploration Plan of Operations #NVN077104

The Sleeper Mine #NVN064100

Class II Air Quality Operating Permit Surface Area Disturbance #AP1041-2831

The reclamation bonds associated with the above activities are:

Exploration Bond #NVB000444 current obligation -$345,044

Reclamation Bond #NVB000330 current obligation $3,966,373-

There are also numerous other permits in place that are maintained from previous mine activities. These are maintained for ease in updating should a decision be made to reinitiate production at the site. Maintenance of these permits includes monthly, quarterly and annual monitoring and reporting. These permits include:

Mine Reclamation Permit #0037

Water Pollution Control Permit #NEV50006

Ground Water Appropriation Permit #53228, #53231 and #53236

Hazardous Materials Permit #30473 FDID #08250 Facility #1168-2326

Class III Solid Waste Landfill Waiver #SWMI-08-10

Industrial Artificial Pond Permit #S34480

Mine Plan of Operations #N64100

The BLM Nevada State Office currently holds BLM bond number NVB00330 with Sleeper Mining Company LLC, as principal, in the amount of $3,966,373; and BLM bond number NVB00444 with New Sleeper Gold LLC, as principal, in the amount of $345,044. The bonds provide surface reclamation coverage for operations conducted by the principal on NVN064100, the Sleeper Mine, and NVN077104, the Sleeper Gold Exploration Plan, respectively. The current obligation was approved 10/09/2020 and is reviewed every 3 years. Paramount is currently in compliance with all issued permits.

3.5 ROYALTIES

A total of five separate Net Smelter Return ("NSR") royalties apply to future production from the Sleeper property as follows:

- The Snyder Syndicate, a private company, holds a one percent (1%) NSR royalty on 1,044 claims in a mining scenario;
- Franco-Nevada U.S. Corporation ("Franco") holds a two percent (2%) NSR royalty on minerals produced from 2,474 mining claims;
- Evolving Gold/Quinton Hennigh holds a 2% NSR royalty;
- Dry Lake Placer Association holds a 3% NSR royalty; and
- ICN holds a 0.5% NSR royalty on the "SS" and "SP" mining claims as well as a 1.5% NSR royalty on the Blue mining claims.

Figure 3-3 shows the areas of the property subject to the royalties summarized above.

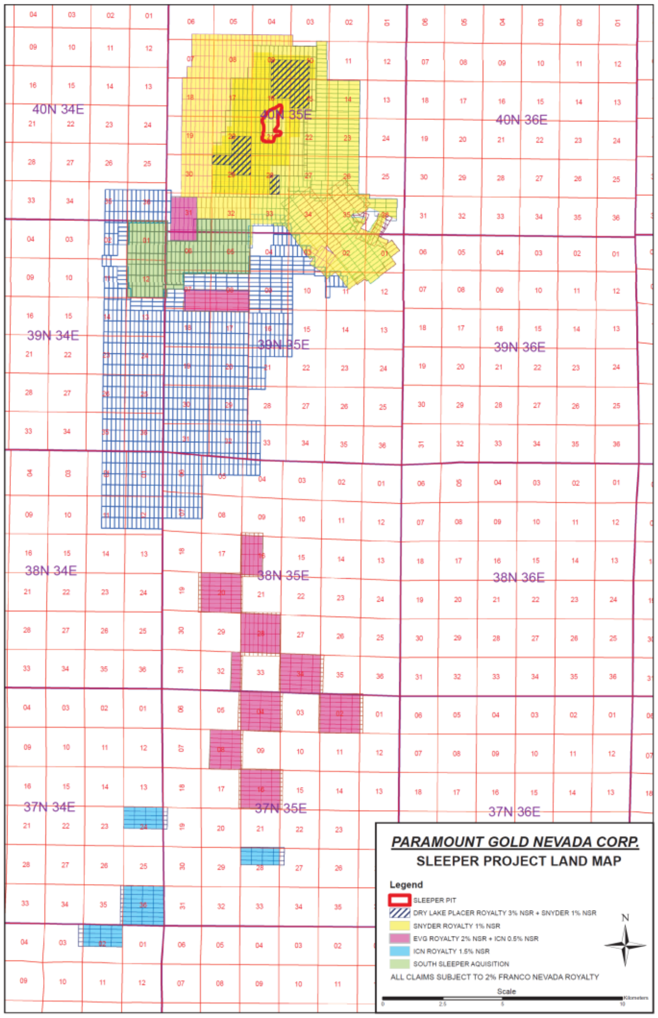

Figure 3-3. Map of Sleeper Property Subject to Applicable Production Royalties

3.6 SIGNIFICANT FACTORS AND RISKS

RESPEC is not aware of any significant factors and risks that may affect access, title, or the right or ability to perform work on the property other than those described in Sections 3.1 through 3.5.

4.0 ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE, AND PHYSIOGRAPHY

4.1 TOPOGRAPHY, ELEVATION AND VEGETATION

The Sleeper gold-silver property is located approximately 50 kilometers northwest of Winnemucca, Nevada on the western flank of the Slumbering Hills. The property covers flat to hilly, grass- and shrub-covered desert, with a few trees present at higher elevations. Elevations range from1,250 meters along the western valley side of the property to 1,646 meters on a hilltop in the southeastern portion of the property.

4.2 ACCESS TO THE PROPERTY

Access to the Sleeper gold-silver property is via Interstate Highway 80 to Winnemucca, north on Highway 95 for 51.5 kilometers, west on Highway 140 for 22.5 kilometers, and then south on the maintained gravel Sod House Road for 10 kilometers to the project site.

4.3 CLIMATE AND LENGTH OF OPERATING SEASON

The climate in the Sleeper property area is semi-arid, with temperatures that are cool to cold during the winter, with occasional moderate snowfalls, and warm during the summer with cool nights. The area is fairly dry, with infrequent rains during the summer. Exploration and mining activities can be conducted year-round.

4.4 INFRASTRUCTURE

An office building, a maintenance building plus assorted equipment are present at the Sleeper project site and are in use for exploration offices, core logging, storage and to support drilling programs. Necessary supplies, equipment, and services to carry out full sequence exploration and mining development projects are available in Winnemucca, Reno, and Elko, Nevada. A trained mining-industrial workforce is available in Winnemucca and other nearby communities. The Sleeper property area is uninhabited. The overall subdued topography that characterizes much of the Sleeper property provides ample ground for the siting of mine facilities, tailings, waste dumps and heap leach facilities.

5.0 HISTORY

The information summarized in this section is taken largely from Redfern and Rowe (2003), Gustin and Fleming (2004), Thomason et al. (2006), Giroux et al. (2009), Wilson et al. (2015), and Ressel et al. (2020). RESPEC has reviewed this information and believes it is suitable for use in this report.

The Sleeper gold-silver project is located in the Awakening district which has been active since the early 1900s. Early production of gold was associated with gold-bearing quartz veins and the district was significantly revitalized with the discovery of the Sleeper deposit by AMAX in 1982, and subsequent open pit mining from 1986 through 1996. This section summarizes historical mining operations, operators, and exploration and development work undertaken by previous owners and operators.

5.1 HISTORICAL PRODUCTION

5.1.1 EARLY MINING: 1914 TO 1982

Early production of gold in the Slumbering Hills (Awakening district), first recorded in 1914, was associated with gold-bearing quartz veins in Mesozoic metasedimentary rocks. Production increased beginning in 1936 with development of the Jumbo and Alma mines (Nash et al., 1995). Narrow quartz-adularia veins within folded metasedimentary rocks were exploited for gold at the Jumbo mine located approximately six kilometers southeast of the Sleeper mine by open pit and underground methods (Nash et al., 1995). Workings including several shafts, adits, and numerous prospects located within 2 kilometers of the eventual Sleeper mine. These old workings, probably from the 1930s, are in or adjacent to altered and veined Tertiary volcanic rocks. The Sleeper mill was constructed atop one of the historical shafts (Nash, et al., 1995). Willden (1964) tabulated a total of 26,262 ounces of gold produced from the Awakening district between 1932 and 1958.

5.1.2 AMAX: 1982 TO 1996

The post-1950s mining history of the Sleeper property, as summarized in Wood and Hamilton (1991), began in 1982 when John Wood, an exploration geologist with AMAX Gold Inc. ("AMAX"), observed iron oxide minerals in a scarp east of what became the Sleeper mine during an aerial geological reconnaissance. AMAX conducted surface geological and geochemical work over the next two years and a drilling program that identified gold mineralization that averaged approximately 1.4 g Au/t. In late 1984, AMAX's thirty-fourth drillhole stepped out to the west of the previous drilling and intersected 102 meters of silicified breccia with an average grade of 27.8 g Au/t and 61.7 g Ag/t, including one very high-grade quartz vein containing abundant visible gold (Nash et al., 1995).

In February 1985, AMAX formally announced the discovery of the Sleeper gold deposit. Mining began in January 1986 and mill commissioning began the following month. On March 26, 1986 AMAX poured its first gold bar. Although the mine plan called for production of about 40,000 ounces in 1986, the mine produced 126,000 ounces of gold during the year at an average cost of less than $60 per ounce, making it one of the lowest cost gold mines in the world at the time.

AMAX's initial capital investment was recouped in the first six months of operation. During the first nine months the head grade was 25.7g Au/t, or more than twice the expected grade, owing to bonanza grades in the Sleeper vein (Redfern and Rowe, 2003). In September 1986, AMAX began processing low-grade material in a heap leach circuit. Production increased to 159,000 ounces in 1987 (the first full year of production) and to 230,000 ounces in 1988 at an average cost of $103 per ounce (Proteus, 2002). Armed guards were hired to protect the high-grade, visible gold in the pit. In 1993, annual production declined to 100,000 ounces of gold at a cash cost of $317 per ounce. Cyprus Minerals and AMAX Inc. merged to form Cyprus AMAX Minerals Co. in 1994. AMAX suspended mining operations at Sleeper in 1996.

The Sleeper operation was designed to treat oxide mineralization by both milling and heap leaching. There was no flotation circuit in the mill to recover gold bearing sulfides. The early pit mill feed was oxide material, but zones of sulfide mineralization were present in the pit. Reported total gold production was 1,219,880 ounces from the mill and 438,609 ounces from heap leaching (Zoutomou, 2007). Silver production totaled approximately 2.3 million ounces.

After production ceased, groundwater has infiltrated into the open pit, forming a pit lake. The pit lake surface is within 34 meters below the crest of the original pit limits. The mill and crushing facilities have been removed and the mill area has been reclaimed.

5.2 HISTORICAL EXPLORATION

The Sleeper deposit was largely overlain by alluvial deposits and was discovered by drilling through only a few meters of unconsolidated post-mineral cover. Over the past 40 years, there have been more than 4,400 exploration holes drilled in and around the Sleeper property by AMAX and numerous other companies. Historical drilling from 1983 through 2012 is summarized in Table 5-1. The majority of drilling has been done with reverse-circulation rotary ("RC") methods which account for 95% of the holes and 93% of the meters drilled on the property. A map showing historical drill collar locations, to the extent known, is shown in Figure 5-1.

Sleeper exploration data includes more than 2,600 rock-chip geochemical samples, more than 11,300 soil geochemical samples, and at least 21 geophysical surveys within the current project landholdings (Ressel et al., 2020). The historical geophysical surveys included gravity, airborne magnetics, ground magnetics, induced polarization("IP")/resistivity("R"), magnetotelluric ("MT"), and seismic studies, as listed in Table 5-2. Surveys completed for Paramount are described in Section 7.1.

Exploration work carried out by historical operators is summarized chronologically below.

Table 5-1. Summary of Sleeper Deposit Drilling in RESPEC Database

Year	Company	Core Holes	Core Meters	RC Holes	RC Meters	RC+Core Tail Holes	RC+Core Tail Meters	Sonic Holes	Sonic Meters	?? Holes	?? Meters	Total Holes	Total Meters

5.2.1 AMAX 1982 - 1998

Exploration efforts by AMAX leading to and following production included surface mapping and geochemical sampling, drilling, and geophysical surveys (e.g., Nash et al., 1995; Wood, 1988; Wood and Hamilton, 1991). From 1983 through 1995, AMAX drilled a total of 494,789 meters in 3,670 RC holes. RESPEC has no information about AMAX's drilling contractors, specific rig types, sample collection methods, or collar and down-hole surveys.

In May 1984, a time-domain IP survey was conducted by DMW Geophysics for AMAX. AMAX used these IP survey data to delineate conductive rock units such as sulfidic or clay-rich zones locally present, and resistive rock units, such as veined areas with silicification (Wood and Hamilton, 1991). In general, the IP survey showed that sulfidic mineralization in the Sleeper pit area could be correlated with IP highs. An IP high was also present along the Range Front fault east of the open pit.

Paramount's drilling data compiled by RESPEC for this report includes nine RC holes drilled in 1989 by "NGM". RESPEC is not aware of the actual name of NGM or its relationship to AMAX. RESPEC has no information about NGM's drilling contractors, specific rig types, sample collection methods, or collar and down-hole surveys.

AMAX merged with Cyprus Minerals to form Cyprus AMAX Minerals Co. ("Cyprus-AMAX") in 1994. Mining operations at Sleeper were suspended in 1996 and in 1998 Cyprus-AMAX merged with Kinross Gold Corporation ("Kinross").

5.2.2 X-CAL RESOURCES LTD 1993 -1997

In 1993, X-Cal acquired property around the Alma underground mine in the Awakening District, southeast of the Sleeper pit. X-Cal acquired additional land in 1994 and 1995, extending its holdings to the limit of the AMAX Sleeper property boundary. In April 1996, X-Cal and AMAX formed a joint venture to explore the Sleeper property, which included the land holdings of both X-Cal and AMAX. Upon entry into the district, X-Cal carried out exploration work progressing from comprehensive compilation of all data, analysis of satellite imagery and low-level aerial photography, detailed geologic and structural mapping, surface geochemical sampling, and ground-generated and airborne geophysical surveys.

From 1993 through 1997, a total of 7,599 soil samples and 2,480 rock chip samples were collected from the Sleeper property by X-Cal (Redfern and Rowe, 2003). RESPEC is not aware of the methods and procedures used for these exploration surveys nor the results.

The database compiled by RESPEC from Paramount's drilling files indicates X-Cal drilled a total of 27,600 meters in 140 holes during 1996 and 1997 (Table 5-1). All of X-Cal's drilling during this time was done with RC methods. Details of the drilling methods and procedures were summarized in Kornze et al. (2006), but RESPEC is not aware of X-Cal's drilling contractors, rig types, or how collar and down-hole surveys were conducted. Although X-Cal was a reputable exploration company, this lack of information imparts risk and affects the classification of the current mineral resources presented in Section 11.

5.2.3 PLACER DOME 1997

In 1997, X-Cal entered into an option agreement with Placer Dome US Inc. ("Placer Dome") that granted Placer Dome the right to earn a 50% interest in the Sleeper project. During 1997, Placer Dome reviewed the Sleeper property data in detail, completed a detailed aeromagnetic survey, and drilled a total of 13,168 meters in 47 holes (Table 5-1). The RESPEC database includes six holes of unknown type for 2,204 meters, as well as 11 holes initiated with RC and finished with core tails. The 1997 drilling was an effort to extend known mineralization as well as discover new zones of mineralization. RESPEC has no information about Placer Dome's drilling contractors, rig types, sample collection methods, or how collar and down-hole surveys were conducted. Although Placer Dome was a reputable exploration company, this lack of information imparts risk and affects the classification of the current mineral resources presented in Section 11.

Pediment and Range Front areas and approximately 60% of other target areas were covered by a detailed airborne magnetic survey completed for Placer Dome. The survey comprised E-W and N-S lines spaced 50 meters apart, with magnetometer recordings every two meters along lines. Local aeromagnetic highs were thought to be associated with volcanic, hypabyssal, or metasedimentary rock units (White, 2003). Placer Dome declined to exercise the option and the property reverted to X-Cal.

In 1997 Mineral Resources Development Inc ("MRDI") implemented studies of the Sleeper mine tailings and heap leach pads for X-Cal. Six auger holes, approximately 7.6 to 10.7 meters deep, were drilled into the tailings. The depth and degree of oxidation was delineated utilizing data from drill samples. A metallurgical study of the heap leach pads included completion of two RC holes and three auger holes in the heap leach pads. The RESPEC drilling database does not include the 1997 auger drill holes as of the effective date of this report and are not included in Table 5-1.

5.2.4 X-CAL 1998 - 2003

Commencing in 1998, X-Cal negotiated a series of options to purchase the Kinross interest in Sleeper. In January 1999, X-Cal carried out a sampling and metallurgical test program on the Sleeper mine tailings (KCA,1999). Ten auger holes (15.2 centimeter in diameter) were drilled in the southeastern end of the tailings pond and samples were obtained from depths of 2.7 to 4.6 meters for metallurgical testing. The RESPEC drilling database does not include the 1999 auger drill holes as of the effective date of this report and are not included in Table 5-1.

In 2002, X-Cal carried out a sampling project to further test the Sleeper mine tailings impoundments. X-Cal drilled 83 sonic drill holes (3.2 to 5.1 centimeters in diameter) to depths of 9.1 to 10.7 meters (the average thickness of the tailings was estimated to range from 12.2 to 13.7 meters). The holes were sampled at intervals of 1.52 meters.

In 2003 a gravity survey was carried out at the Sleeper property by Geophysical and Geodetic Associates Inc. of Reno, Nevada for X-Cal. The survey comprised east-west and north-south lines spaced 500 meters apart with gravity measurements every 200 meters along lines. Interpretations were refined following additional gravity surveys for New Sleeper Gold in 2004 as described in the next section.

5.2.5 NEW SLEEPER GOLD 2004 - 2006

In January of 2004, New Sleeper Gold Corp. ("New Sleeper") formed a 50/50 joint venture with X-Cal Resources by acquiring Kinross Gold's 50% interest in the Sleeper property. New Sleeper assumed management of the Sleeper property as the "Sleeper JV". RESPEC's drilling database attributes a total of 18,041 meters of drilling to New Sleeper in 2004 and 2005. The drilling included 20 core holes, 45 RC holes, and four holes of unknown type. According to Giroux et al. (2009), the New Sleeper drilling also included 688.8 meters of sonic drilling, presumably in the waste dumps or tailings impoundment. The data for this sonic drilling has either been lost or has not been compiled by Paramount. Further uncertainty stems from Giroux et al. (2009), who stated:

> "The Sleeper JV drilled a total of 122 holes at Sleeper in 2004 and 2005. Core drilling, reverse circulation drilling and sonic drilling were completed. Table 13.1A below provides footage details of each type of drilling by the Sleeper JV."

Table 5-3. 2004 and 2005 Drill Footage Summary
(from Giroux et al., 2009)

Type of Drilling	Number of Holes	Footage
Core Drilling	57	70,841
RC Drilling	48	29,978
Sonic Drilling	17	2,260
Total	122	103,019

RESPEC is unaware of the drilling contractors, rig types, sample collection methods, or how collar and down-hole surveys were conducted in the drilling by New Sleeper. RESPEC recommends that Paramount fully compile and evaluate this information, to the extent it is available.

New Sleeper conducted trenching, electrical geophysical surveys (both IP and MT), ground gravity surveys, 'Quicksilver' mercury soil gas surveys, O_2/CO_2 soil gas surveys, geological mapping, extensive soil geochemical sampling, and aerial photography (Giroux et al., 2009).

Results from the gravity surveys of 2003 (X-Cal) and 2004 showed significant density contrast between the local basement composed of Mesozoic metasedimentary rocks, and the combined package of pediment and Tertiary volcanic rocks, providing depth to basement determinations (Thomason et al., 2006). Additional detailed gravity work in 2005 resulted in improved definition of structures and understanding of the Sleeper deposit. Wright (2005) interpreted residual gravity results to reflect a complex structure involving three primary orientations: north-south, northwest and northeast. The Sleeper deposit appeared to be located at the intersection of northwest and northeast structural corridors, proximal to a major north-south oriented basement feature.

A natural source MT survey was conducted over the "NW and SW Pediment areas" by Quantech who also modeled results. Additional modeling of these data by Wright (2005) yielded preliminary interpretations of subsurface geology, structure, and possible alteration.

From 2004 through 2006, approximately 55 line-kilometer IP and resistivity surveys were completed by Zonge Geosciences Inc. ("Zonge") and Quantech Consulting Inc. ("Quantec"). Zonge and Quantech processed their respective data, and calculated 2D model inversions of the results. The inversions were forwarded to Jim Wright for geophysical interpretation (Thomason et al., 2006).

Wilson et al. (2015) stated:

> "In 2004 New Sleeper completed 17 sonic drill holes (13 vertical) for a total of 641.6 meters in Leach Pad 1. All holes terminated at least 6.1 meters above the leach pad liner as required by State of Nevada regulations."

The above is not consistent with the drilling data received from Paramount, or possibly Paramount has not compiled the New Sleeper drilling data completely.

In 1997, Placer Dome conducted a pilot clay mineralogy study on 49 drill holes using Terra Spec ASD short-wave infrared ("SWIR") spectral analyses. The study identified a strong association between gold mineralization and ammonia minerals including NH4-illite and buddingtonite. In 2004, New Sleeper Gold expanded on Placer Dome's pilot clay mineralogy study and gathered spectral data from approximately 250 drill holes, but RESPEC is not aware of the results or significance of this work.

Between 2004 and 2005, a variety of surface geochemical surveys were carried out. Two phases of mercury vapor surveys were completed in 2004 and 2005 as a reconnaissance tool to detect possible mineralization beneath the pediment surface. The surveys covered the entire pediment area of the Sleeper property west of and overlapping the interpreted Range Front fault. Rock chip and soil samples were collected during this period, and results were added to existing databases; as of 2006 the databases included a total of 1,762 rock chip samples and 9,866 soil samples from the property area. RESPEC has not evaluated these data and is not aware of the results.

Under the management of New Sleeper, the mill and crusher facilities were removed and the sites where these facilities formerly stood were reclaimed. New Sleeper and X-Cal equally funded work at Sleeper from August 2005 to May 2006, at which time X-Cal purchased New Sleeper's 50% interest in the project for a combination of cash and X-Cal common stock. The Sleeper property was then consolidated 100% into X-Cal until August 2010.

5.2.6 X-CAL 2006-2010

According to Giroux et al. (2009), core drilling procedures used by X-Cal during 2007 were as follows:

> "Core was collected by a truck mounted Atlas Copco CS3001 core rig capable of drill depths in excess of 2,000 feet. The drill equipment was owned and operated by EMM Core Drilling of Winnemucca, Nevada. Corrugated waxed cardboard core boxes were provided by the core contractor. Wooden blocks or plastic depth indicators were labeled and placed by the core contractors at the appropriate measured drill depths.
>
> Preferred core size was HQ. Adverse drilling conditions preventing advancement of the HQ tools was remedied by casing the hole down to the problem zone. Occasionally a reduction to NQ tools was needed to continue the drill hole to targeted depth.

Core holes drilled in the West Wood target were pre-collared and cased to bedrock (approximately 160-210 feet) using the RCD rig. Angle and vertical drill hole collar sites were pre-surveyed using a portable GPS positioning device.

Completion of each core hole was preceded by down hole surveys conducted by International Directional Services of Battle Mountain, Nevada. After the completion of the drill hole and down hole survey the hole was abandoned by pumping a bentonite slurry from the bottom of the drill hole to within 10 feet of the surface. The remaining surface plug was ten feet of Portland cement. Desert Mountain Surveying of Winnemucca, Nevada, conducted surface collar surveys for each core hole.

Core boxes filled with core were neatly stacked upon pallets and tarped at the drill site until the full pallet was transported to the core processing facility. The core was washed, geologically logged and sample intervals selected and labeled by the core geologist.

The next procedure was digitally photographing the core in place utilizing scale bars to easily position the exact down hole location within each individual core box. The core boxes were then positioned next to the sheds that contain self-feeding core saws.

Each piece of silicified or hard core is placed in a confinement jig. The maximum length is one foot. The jig positions the core's central axis producing two nearly exact volumetric halves after the core has been cut. One core half is returned to its origin box and the remaining half is placed into a pre-marked 16"X19" sample bag. The more clay rich core intervals are hand chiseled into halves by the core technician or by a geologist.

The sampling technician independently logged the core sample intervals. Copies of the sample intervals are submitted to the assay lab and a copy is archived into individual core hole folders. In addition, the folders contain copies of the geologic log, down hole survey, assays, hole abandonment sheets and surface collar surveys."

Giroux et al. (2009) stated that X-Cal's RC drilling procedures in 2007 were as follows:

"The reverse circulation drilling (RC) programs for both late 2006 and 2007 have utilized a Schramm 685, capable of drill depths in excess of 2,500 feet. The Schramm rig is owned and operated by DeLong Drilling and Construction of Winnemucca, Nevada. The crew consists of one driller and two driller's helpers. The driller's helpers have multiple tasks in addition to their mechanical drilling duties which include sample bag numbering (including duplicates), chip tray numbering, sample and chip collection and sample storage at the drill site. All drill hands are responsible for a safe, clean and organized drill site.

The preferred RC drill hole diameter is 5 ¾ inches produced by a pneumatic hammer and carbide button bit. If water volumes exceed capacities that prevent the advancement of the hammer tool or adverse conditions warrant the use of a tricone tool, the hammer tool is tripped out of the hole and the appropriate tri-cone diameter is returned to the bottom of the hole.

Occasionally a reduction to a smaller diameter of tri-cone is needed to complete the proposed drill hole.

Depths to bedrock vary according to target location. Shallow bedrock depths (less than 20 feet) require only one 20-foot length of 6 inch inside diameter thick-walled casing. Moderate depths to bedrock (over 20 feet and under 250 feet) are cased using a conventional (weld, hammer drive, weld) casing technique. After recent sediments (sands, basin fill sand and gravels) reach accumulations in excess of 250 feet casing depth is dependent upon the sediment's integrity (adhesive, cementation and porosity properties) and water volumes encountered. All drill holes drilled atop of mine dumps or other areas previously used as staging areas for ore (crusher sites, mill site, etc.) are cased through the mine dump fill material into bedrock at least 10 feet.

RC samples are collected from the surface every 5 feet. Provided an area has previous drilling results that warrant the over burden not to be sampled, an appropriate estimate to sample depth is provided to the driller. Duplicate samples are collected from the rotary splitter every 150 feet.

The rotary wet splitter (splitter) is attached to the rear passenger side of the Schramm. The splitter is washed down after each completed drill hole. Once surface casing is completed water and on demand drilling mud and hole conditioners are injected to suppress silica dust exposure and maintain the integrity of the drill hole.

The splitter has removable pie shaped platelets that are removed or added to maintain a consistent 20:1 volumetric split product at the exit end of the sample collection port. The sample exits the port straight downward into a 5-gallon plastic bucket. Once the 5 feet drill interval has been completed another clean bucket is placed under the exit port. The sample bucket is poured into a pre-labeled 15 inch by 17-inch sample bag. The sample bucket is rinsed once with fresh water and contents poured into the sample bag. The bag is tied and placed into a collection crib or crate that has been provided to the project by American Assay. The crib provides an additional assurance against contamination by ground exposure. The duplicates taken every 150 feet are collected by similar procedure and placed upon a black plastic sheet for drill site storage.

Drill rod changes have long been suspected for down the hole contamination during RCD drilling on other projects. At Sleeper the end of the 20 feet drill rod cycle is used to ream, clean, and dress the walls of the last 20 feet drilled. The process takes a few moments but is vital in maintaining a clean drill hole. Once the new rod for the next 20 feet is positioned, the rotation is started and down the hole pressures and water levels are allowed to stabilize. A screen is placed at the exit of the splitter and checked for debris that may have its origin from up hole. The sample bucket is re-positioned under the sample port only after the driller observes a clean return in the screen. This method takes additional time and has been proven to be a very effective method in minimizing down the hole contamination.

Completion of each RCD hole was preceded by down hole surveys conducted by International Directional Services of Battle Mountain, Nevada. After the completion of the drill hole and down hole survey the hole was abandoned by pumping a bentonite slurry from the bottom of the drill hole to within 10 feet of the surface. The remaining surface plug was ten feet of Portland cement. Desert Mountain Surveying of Winnemucca, Nevada, conducted surface collar surveys for each RCD and core hole.

Compartmental chip trays (20 compartments) were used to archive drilled material from each 5 feet of drill advancement. Each compartment's content was pre-washed prior to filling the compartment with the aid of a fitted funnel. The process minimizes any contamination from other 5 feet samples. Prior to completion of an RCD hole, the chip trays were stored and secured by the drillers at the rig site after drilling hours. All chip trays were collected after completion of each specific RCD hole. Note: The fenced compound is locked after day shift ends and remains locked until day shift resumes the following day. During the day period the electric gate is unlocked and accessible to entry only through Sleeper personnel.

All chip tray intervals are reviewed by at least one geologist and logged for geologic attributes. The chip trays are archived by drill hole number and placed upon steel shelves located in closed buildings for later additional reviewing."

5.2.7 EVOLVING GOLD 2007 - 2008

In 2008, Evolving Gold completed an extensive exploration and drilling program over an area to the south of the Sleeper deposit entirely covered by unconsolidated alluvium and lake sediments (Ressel et al., 2020). According to a press release, the program was designed to test targets with relatively shallow cover and decreased magnetic response. Evolving Gold drilled 34 RC holes for a total of about 6,636 meters, although there are several collar files with inconsistent information (Ressel et al., 2020). Four holes failed to reach bedrock; the other holes terminated in basalt, volcaniclastic sediments, Mesozoic metasedimentary rocks, or Mesozoic granite (Ressel et al., 2020). The Evolving drilling program was not successful. There were a few drill holes with gold in the tens of ppb – not worth following up. Paramount has not compiled and evaluated this information and none of the Evolving Gold drill holes are included in the RESPEC database as of the effective date of this report. RESPEC is not aware of the drilling contractors, rig type or methods and procedures used by Evolving Gold. RESPEC recommends that Paramount compile and fully evaluate the Evolving Gold drill data for future studies of the Sleeper property.

Evolving Gold contracted a significant quantity of geophysical surveys, including seven lines of IP, two blocks of ground magnetics, and 396 gravity stations. This data was all provided to Paramount and evaluated by Mr. James Wright. Evolving Gold was exploring for another Sleeper deposit, targeting areas with shallower bedrock cover and reduced magnetic signature, which was interpreted to be from magnetite-destructive alteration.

5.2.8 MONTEZUMA MINES 2009-2012

Ressel et al. (2020) reported:

> "Paramount has recently acquired a property explored by Montezuma Mines and most recently held by South Sleeper Resources LLC. The property consists of 152 unpatented lode mining claims (60 RO claims and 92 SH claims) that cover an area of about 12.6 square kilometers located about 2 km south of, and extending into, the Paramount property position.
>
> The entire property is located to the west of the Slumbering Hills with no outcrop. In their exploration of the property, Montezuma Mines completed IP/Resistivity surveys, ground magnetic surveys, and extensive soil and soil gas geochemistry. The company drilled 11 holes for a total of 6,366 feet of core in 2011 and 2012. The core was analyzed for multielement geochemistry, with clay characterization by reflectance spectroscopy."

Paramount has not compiled the Montezuma Mines drilling data and the 2011-2012 drilling is not included in the RESPEC drilling database as of the effective date of this report. RESPEC recommends that Paramount compile and fully evaluate the Montezuma Mines drill data for future studies of the Sleeper property.

5.2.9 PARAMOUNT GOLD AND SILVER CORP. ACQUISITION 2010

Paramount Gold and Silver Corp. acquired all the issued and outstanding shares of X-Cal in August 2010 by plan of arrangement. In 2013, X-Cal changed its name to Paramount Nevada Gold Corp. which was merged into Paramount Gold Nevada Corp. in early 2015. In December 2014 Paramount Gold and Silver Corp. entered into a merger agreement with Coeur Mining, Inc. ("Coeur"), Hollywood Merger Sub, Inc. and Paramount Gold Nevada Corp. pursuant to which Coeur acquired Paramount Gold and Silver after the spin-off of Paramount Gold Nevada Corp. (Paramount) owning 100% of Sleeper Mining LLC and New Sleeper LLC. Paramount's exploration from 2010 through the effective date of this report is summarized in Section 7.0.

5.3 HISTORICAL MINERAL RESOURCE ESTIMATES

Several estimates of mineral resources at the Sleeper property were completed between 1985 and Paramount's acquisition of the property beginning in 2010. The sources of these historical estimates are summarized in Table 5-4. The citations for historical resource and reserve estimates in this section are presented as an item of historical interest only and should not be considered representative of actual mineral resources or mineral reserves currently present at the Sleeper property. The current mineral resources for the Sleeper deposit are discussed in Section 11 of this report.

Table 5-4. Summary of Historical Mineral Resource Estimates, Sleeper Property

Company	Year	Reference
AMAX	1985	Wood and Hamilton, 1991
AMAX	1989	Wood and Hamilton, 1991
Placer Dome and X-Cal Resources	1997	Mineral Resources Development, Inc. ("MRDI"), 1997
X-Cal Resources	1999	Sierra Mining and & Engineering LLC ("Sierra"), 1999
X-Cal Resources	2009	Giroux et al., 2009

6.0 GEOLOGIC SETTING, DEPOSIT TYPE, AND MINERALIZATION

6.1 REGIONAL GEOLOGIC SETTING

The Sleeper project area is situated along the western Slumbering Hills within the western northern Nevada rift, a northwest-trending geologic province extending from southeastern Oregon to southeastern Nevada. The northern Nevada rift is a narrow region of mid-Miocene-age bimodal basalt-rhyolite volcanism, rifting, and widespread low-sulfidation epithermal mineralization (John, 2001).

In general, pre-Miocene rocks in the Slumbering Hills consist of metasedimentary rocks of the Auld Lang Syne Group and granitic intrusions. Metasediments of the Auld Lang Syne Group were part of an early Mesozoic back-arc basin sequence deformed and metamorphosed to greenschist facies during late Jurassic contraction related to the Luning-Fencemaker east-directed thrust belt (Willden, 1964; Burke and Silberling, 1973; Oldow, 1984; Wyld et al., 2002). In the central part of the Slumbering Hills, a granodioritic to monzonitic pluton was emplaced during the Cretaceous (Willden, 1964).

Tertiary volcanic rocks and intercalated sedimentary rocks unconformably overlie and intrude rocks of the Auld Lang Syne Group in the northern and eastern parts of the Slumbering Hills. Many of the Tertiary volcanic units are thought to be outflow facies of the McDermitt volcanic field and related calderas to the north, with the volcanic rocks that host the Sleeper deposit originating from a local volcanic complex (Nash et al., 1995). Quaternary pediment gravels and eolian sands lie to the west of the Slumbering Hills and cover much of the Sleeper project area.

Basin and Range extension was first manifested in lacustrine and alluvial volcaniclastic materials deposited prior to 17 Ma, and in numerous high-angle normal faults with northerly to northeasterly strikes. Although Auld Lang Syne rocks are significantly deformed at small scales, district-wide tilts in the northern Slumbering Hills suggest the principal structure is a northeast-trending arch or anticline with a southeast-dipping east limb and a northwest-dipping west limb (Nash et al., 1995).

6.2 DISTRICT AND LOCAL GEOLOGY

The Sleeper project is located on the western flank of the northern Slumbering Hills and sits largely within the adjacent Desert Valley to the west. The project area encompasses more than 180 square kilometers (Figure 3-2). Quaternary gravels, alluvium, colluvium, and a surficial sequence of eolian sand infilled the Desert Valley and cover much of the Sleeper deposit.

The Sleeper project straddles a major west-dipping range-front normal fault along the northern Slumbering Hills (Wood, 1988; Nash and Trudel, 1996). This principal fault (the "range-bounding fault") has a total displacement up to 1,000 meters in the western Desert Valley hanging wall (Hudson, 2014b) and the Sleeper gold-silver mineralization is situated nearly entirely in the hanging wall. In the deposit area, this main range-bounding fault is interpreted by Hudson (2013a, 2013b) to dip at approximately 45° West and to separate Mesozoic metasedimentary rocks of the Auld Lang Syne Group in the footwall from middle Miocene lavas, flow breccia, and lesser epiclastic and tuffaceous rocks in the hanging wall. Previous workers (e.g., Wood, 1988; Nash et al., 1991; 1995; Nash and Trudel, 1996) interpreted an approximately 45° West depositional contact between basement Auld Lang Syne and the overlying

Miocene volcanic rocks, which were cut dominoes-style by numerous steep (>70°) west-dipping normal faults including the range-bounding fault. The current Sleeper geological model uses the interpretation of Hudson (2013a, 2013b; 2014a, 2014b).

Basement rocks of the Auld Lang Syne Group in the Sleeper area are subdivided into a basal calcareous phyllite, a middle unit of argillite and phyllite, and an upper unit of fine- to coarse-grained quartzite with lesser phyllite (Ferdock et al., 2005). These rocks exhibit pervasive slaty cleavage and contain abundant muscovite from recrystallization during regional metamorphism. The Auld Lang Syne Group has a structural thickness of well over one kilometer near the Sleeper project. Rocks of the Auld Lang Syne Group host the gold-bearing quartz-adularia veins that were exploited at the Jumbo and Alma mines.

Commented [MN3R2]: I see figure titles above and below the image, I think we should be consistent

Tertiary volcanic rocks (Nash et al., 1985) unconformably overlie and intrude Auld Lang Syne metasediments in the northern and eastern parts of the Slumbering Hills. The basal unit is a sequence of volcaniclastic rocks and local volcanic flow strata of intermediate composition up to 200 meters in thickness. The age of this unit is uncertain, but pre-dates a 17.3 Ma quartz-adularia vein cutting this unit at the Jumbo mine to the southeast of the Sleeper mine (Conrad et al., 1993).

A sequence of intermediate volcanic flows and dacitic to basaltic flow breccias overlying the basal volcaniclastic unit is approximately 150 meters in thickness. The Sleeper rhyolite, the main host of gold mineralization within the Sleeper pit, overlies the basalt unit. The Sleeper rhyolite is a sequence of flows, dikes, sills and flow domes of quartz-eye rhyolite with sanidine phenocrysts and local biotite. The age of the Sleeper rhyolite is approximately 17 Ma, but there are no direct age dates (Nash et al., 1995). Rhyolite to quartz latite dikes and sills of similar appearance are found to the east and southeast of the Sleeper mine in the Slumbering Hills.

The Sleeper rhyolite is overlain by significant volumes of peralkaline rhyolite ash flow tuff erupted at approximately 16.2 to 16.1 Ma (Conrad et al., 1993). This strongly welded outflow unit originated from the McDermitt caldera area about 80 kilometers to the north; outcrops can be seen in the northern Slumbering Hills where it is up to about 75 meters thick. Southeast of the Sleeper mine, the Awakening rhyolite of approximately 13.6 Ma (Conrad et al., 1993) appears to have formed several flow domes along normal faults with thicknesses of up to approximately 180 meters. These rocks are generally unaltered, in contrast to the strongly altered flows of the Sleeper rhyolite (Nash et al., 1995). Some silicified but unmineralized intrusive dikes of Awakening rhyolite occur near the flow domes.

The middle Miocene basalt and rhyolite lavas, domes, and small-volume tuffs of the Slumbering Hills and Desert Valley are collectively referred to as the Sleeper volcanic center ("SVC"), which has a known extent of approximately 40 square kilometers. The SVC is spatially and genetically linked to epithermal deposits in the Slumbering Hills, which include the Sleeper deposit and deposits exploited at the Jumbo, Alma, and Mohawk mines to the southeast (Figure 6-3). The Sleeper mineralization is closely associated with rhyolitic dikes and domes of the SVC.

Pliocene basalt dikes occur locally southeast of the Sleeper mine and represent the youngest igneous unit recognized in the Slumbering Hills. Older alluvium (Pliocene to Quaternary; Nash et al., 1995) occurs in the Sleeper project area. This includes gravel containing weathered clasts with quartz veins and visible gold cover the Sleeper deposit. Airfall tuff dated at 2.1 Ma locally overlies the Pliocene alluvium (Conrad et al., 1993). Younger Quaternary pediment gravels, alluvium, and colluvium overlie the Pliocene tuff and occur along the flanks of the Slumbering Hills and as infill within Desert Valley. A capping of eolian sand covers much of the Desert Valley and adjoining hills.

In 2013, Paramount initiated a re-logging program of drill core and RC chips. Based on their work, the following descriptions reflect the current interpretation of the lithologic and structural setting at Sleeper. A stratigraphic column based on that interpretation for the property area is shown in Figure 6-2.

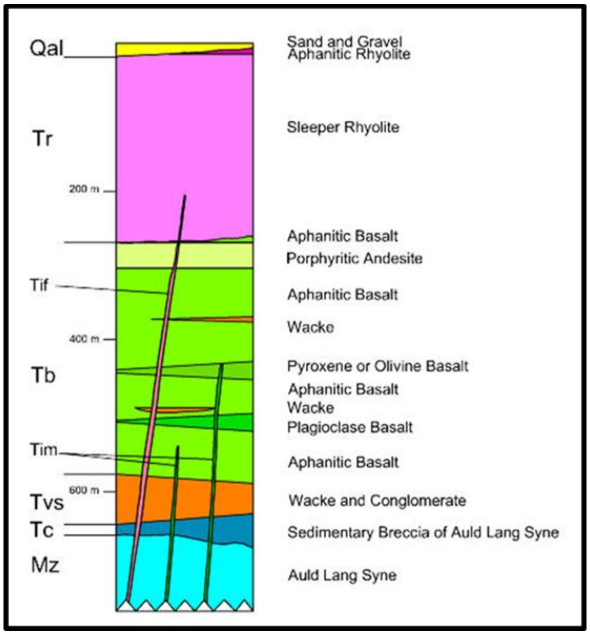

Figure 6-2: Stratigraphic Column for the Sleeper Property
(from Wilson et al., 2015)

The following descriptions summarize the stratigraphic column in Figure 6-2:

- **Qal:** Includes alluvium (sand and gravel) and waste dumps. Gravel of both volcanic and metasediments dominate near the bedrock contact. These are interbedded with eolian sand towards the surface. Near the Range Front fault, metasediments dominate the gravels. This alluvial unit varies from less than 1 meter to >200 meters in thickness southwest of the Sleeper pit.
- **Tr:** Includes the Sleeper rhyolite and possible younger rhyolite flows. Includes vitric and non-vitric rhyolite or dacite with up to 20% plagioclase phenocrysts ranging from <2 millimeters and rarely up to 9 millimeters; trace sanidine and quartz phenocrysts. Contains 3 to 5% (rarely up to 15%) mafic phenocrysts, usually ranging from <1 millimeter and rarely up to 2 millimeters; typically obscured by alteration. In the least-altered rocks, orthopyroxene is slightly more abundant than biotite.
- **Tif:** Felsic intrusions similar to the Sleeper rhyolite, but usually with fewer phenocrysts; may lack quartz phenocrysts. Forms numerous dikes; some intrusions develop into sills or possibly laccoliths.
- **Tb:** This unit is dominantly comprised of basalt flows to basaltic andesite. Individual flows vary from a few meters to up to 100 meters thick. Most tops of flows are highly vesicular and commonly display aa-style textures. Few flows do not contain vesicles. Rocks are aphanitic or contain rare, small phenocrysts. Some flows have up to 7% mafic phenocrysts of augite and/or

olivine <0.5 millimeters in size. Others may have up to 5% plagioclase phenocrysts <1 millimeter in size. Near the top of the mafic sequence of flows is a distinctive andesite or dacite with about 10% highly elongate, small plagioclase phenocrysts. Interbedded with the flows are typically discontinuous volcanic wacke typically less than 20 meters thick. There are also debris flows of mafic material and rare mafic tuffs. The entire sequence likely exceeds 300 meters in thickness.

- **Tim:** Mafic dikes (basalt to basaltic andesite), usually aphyric to aphanitic. These intrude the Sleeper rhyolite, but many are probably older. At deeper levels, particularly in the metasedimentary units, these dikes appear as fine-grained diabase to gabbro with augite and olivine.
- **Tvs:** Wacke, usually fine-grained and rarely laminated. The upper part is a volcanic wacke. With depth, thin, flat clasts of Mesozoic Auld Lang Syne metasediments become intermixed, usually as distinctive fine-grained conglomerate beds; the unit becomes more quartz-rich near the base. In the north-central part of the Sleeper pit, this unit may exceed 150 meters in thickness, but elsewhere is tens of meters thick. Underlying the wacke is a unit of breccia up to 50 meters thick of Auld Lang Syne clasts, which may contain interbedded wacke; this breccia unit overlies the Auld Lang Syne Group in the northeastern part of the Sleeper pit.
- **Tc:** Breccia containing angular clasts of Auld Lang Syne metasediments up to 1 meter in size. Rarely contains interbedded basaltic wacke. Thickness ranges between 0 to 50 meters.
- **Mz:** Weakly-metamorphosed carbonaceous, phyllitic, siltstones and fine-grained, arkose to quartz arenite of the Auld Lang Syne Group. Very rarely carbonaceous, silty; limestone is locally interbedded and usually intensely folded. Intruded by Mesozoic mafic to felsic dikes and sills.

A geologic map of the SVC and a cross-section through the Sleeper mine area are shown in Figure 6-3 and Figure 6-4, respectively.

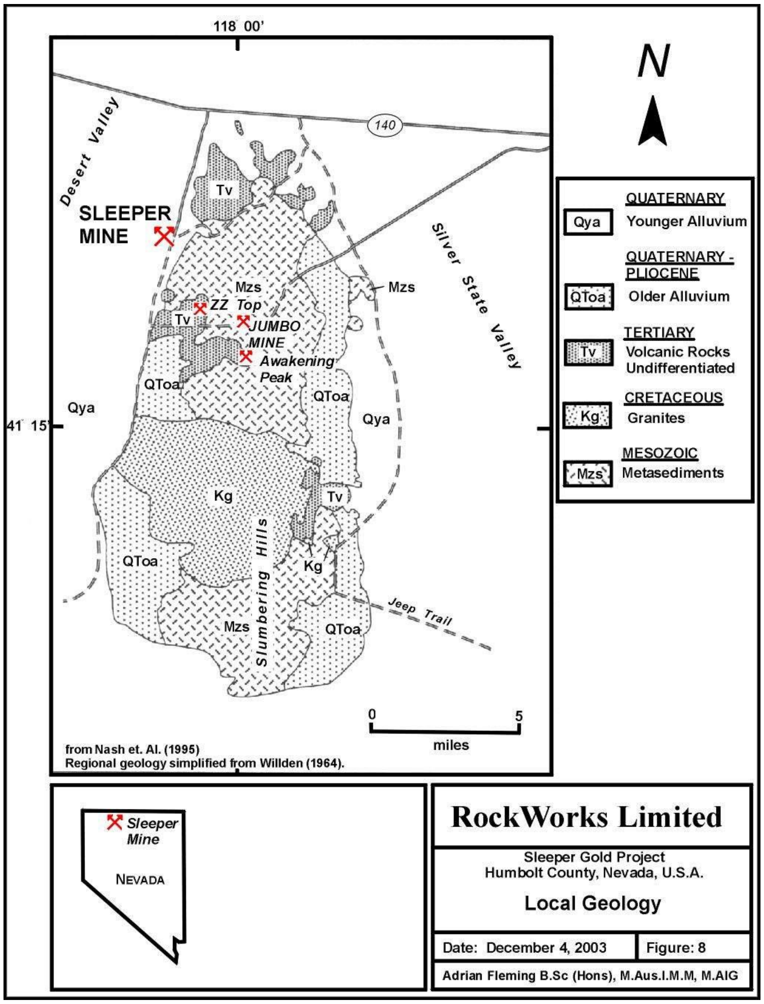

Figure 6-3: Geologic Map of the Sleeper Volcanic Center
(from Nash et al., 1995)

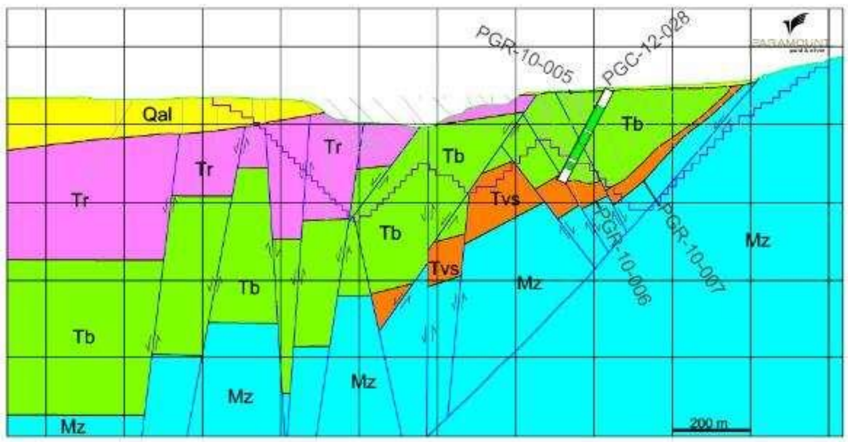

Figure 6-4: Cross-Section looking North through the Sleeper mine area
(from Wilson et al., 2015)

6.3 MINERALIZATION

Gold-silver mineralization in the Sleeper deposit occurs within a zone of relatively large displacement normal faults adjacent to and west of the Range Front fault. The Sleeper deposit consists of four spatially overlapping types of gold-silver mineralization (Nash et al., 1995; Kornze and Phinisey, 2002):

- Banded quartz-adularia-electrum-(sericite) veins;
- Silica-pyrite-marcasite cemented breccias;
- Quartz-pyrite-marcasite stockworks; and
- Alluvial gold-silver placers in Pliocene gravels.

A network of low-displacement faults extends approximately 1,000 meters west in the hanging wall of the principal Range Front fault. This array of faults cuts and displaces stratigraphy within the Sleeper deposit; some faults host ore and other faults truncate ore zones. The Sleeper veins generally dip to the west at moderate to high angles, but some secondary hanging wall offshoots of the principal vein structures dip steeply to the east. The Sleeper deposit is draped by several meters of unconsolidated post-mineralization cover and is generally not exposed in outcrop.

Prior to mining, significant zones of mineralization at Sleeper extend for about 1,500 meters along strike and about 600 meters of width (Wood, 1988). Mineralization persists from near the pre-mining surface to depths of more than 610 meters (Hedenquist, 2005). At least eleven veins with bonanza grades were mined historically. By far the most productive were the "Sleeper Main", "East" (i.e., "Wood"), "West", and "Office Pit" veins. The Sleeper Main vein produced more than 0.5 Moz of gold from a single bonanza ore shoot, which had a strike length of 850 meters and width ranging from 0.3 to 4.6 meters. Level plans of bonanza-grade veins show they collectively encompass an area approximately 1,200 meters long by 450 meters wide. Most discrete bonanza zones consisted of a series of sheeted chalcedonic quartz veins distributed over cumulative widths of 10 to 25 meters. Individual veins ranged in thickness from a few centimeters to locally 5 meters. The bonanza part of the Sleeper Main vein (34 g Au/t) extended from near the top of bedrock to depths of about 213 meters; below that, the vein irregularly contains grades of as much as 8 g Au/t to depths of about 460 meters. Higher-grade vein- and breccia-hosted mineralization are localized at and near structural intersections and flexures in fault orientation.

Gold-silver mineralization is associated with marcasite and occurs as electrum and as visible particles within banded quartz veins. Antimony minerals including stibnite and kermesite are commonly identified proximal to and within more anomalous gold zones. Auriferous, banded quartz veins occur and are predominantly easterly dipping and crosscut quartz-sulfide altered volcanic strata. The banding texture is derived from multiple stages of fluid transport saturated with silica and sulfides. Commonly, bands of dark sulfides and framboidal marcasite are parallel to the microcrystalline quartz bands.

Quartz veins with high gold-silver grades at Sleeper extended up to the unconformity with overlying gravels, indicating significant post-mineralization erosion. Concentrations of alluvial gold on the down gradient or west side of the Sleeper deposit also indicate erosion of the top of the Sleeper veins. Alluvial gold is generally most abundant near the base of the alluvial cover, but at least locally may occur more than 200 meters above the bedrock unconformity.

The Sleeper deposit occurs within a large volume of highly altered rock characterized by magnetite-destructive alteration and abundant clay. Prior to mining, the Sleeper rhyolite was the principal host rock (Nash et al., 1991). The vesicular character and high iron contents of the Miocene basalt promoted the precipitation of pyrite and marcasite through sulfidation reactions. This rendered the basalt receptive to sulfide-breccia-style mineralization. The brittle and less permeable character of the Sleeper rhyolite rendered it favorable for high-grade vein mineralization.

Comprehensive reviews of the Sleeper deposit by Jackson (2006) and Jackson and Chevillon (2007) documented the chemical and alteration zonation within and immediately surrounding the Sleeper deposit. These reviews indicate the presence of a cluster of hydrothermal foci within the Sleeper deposit footprint surrounded by large, encompassing haloes of hydrothermal alteration, which are greater than 2 kilometers in diameter.

Age determinations from adularia indicate precious-metal mineralization at Sleeper formed between about 13.7 and 16.1 Ma (Conrad et al., 1993), similar to, but also much younger than, the16.3 Ma Sleeper rhyolite and underlying basaltic host rocks. A simplified cross-section model of the ore controls, mineralization, and alteration in the Sleeper deposit is shown in Figure 6-5.

The post-mining Sleeper deposit is predominantly characterized by extensive, low-grade stockwork mineralization hosted within the Sleeper rhyolite and underlying basalts. The stockwork mineralization has numerous, randomly oriented quartz-pyrite-marcasite veinlets peripheral to mid- to high- grade veins and breccias. The mid-grade mineralization consists of clast-supported breccias and narrow veins which extend down-dip from previously mined high-grade veins. These mid-grade narrow veins typically assay between 3 and 34 g Au/t, whereas the stockwork assays usually result in grades less than 3 g Au/t.

The West Wood area to the southwest of the Sleeper pit contains high-grade mineralization within a hydrothermal breccia body associated with faults and a felsic porphyritic intrusive. This zone likely represents a down-faulted block that was continuous or parallel to the West vein mined in the pit. The

West Wood breccia is highly silicified with abundant sulfides, but localized veins within the breccia can exceed 100 g Au/t.

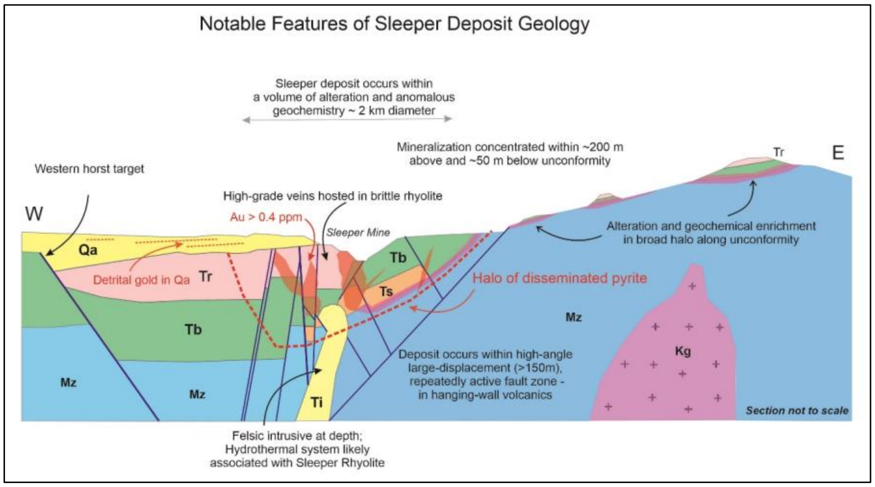

Figure 6-5: Schematic Cross-Section Model of the Sleeper Deposit
(modified from Ressel et. al., 2020. Not to scale. Volcanic occurrences shown to the east in the Slumbering Hills may be more vertically extensive than shown.)

6.4 DEPOSIT TYPES

Sleeper and other occurrences of gold-silver mineralization in the Slumbering Hills (e.g., Jumbo, Alma, and Mohawk) (Figure 6-3) have long been considered examples of epithermal precious-metal deposits (Wood, 1988; Nash et al., 1991; Conrad et al., 1993) that are now classified as the "low-sulfidation" type (e.g. White and Hedenquist, 1995; Hedenquist et al. 2000; Cooke and Simmons, 2000; Sillitoe and Hedenquist, 2003). Sleeper and other low-sulfidation deposits in the region are broadly related to middle Miocene (~17-15 Ma) bimodal basalt-rhyolite volcanism of the SVC associated with the northern Nevada rift (John, 2001). Epithermal deposits are important sources of gold and silver that form at shallow depths (<1.5 kilometers), at temperatures less than 300°C, and in hydrothermal systems commonly developed in association with calc-alkaline to alkaline, as well as continental tholeiitic (i.e., bimodal), magmatism (Simmons et al, 2005). Such deposits can have substantial precious-metal production (e.g., many deposits produce >5 Moz gold and >250 Moz silver) and are particularly known for the spectacular bonanza grades of some deposits (Cooke and Simmons, 2000).

Minerals associated with precious-metals in low-sulfidation systems include pyrite, sphalerite, arsenopyrite, gold-silver sulfosalts, electrum, and gold. Common gangue includes quartz, opal-CT, adularia, calcite, illite, and barite (White and Hedenquist, 1995). Gold typically occurs as electrum in association with silver sulfosalts, base-metal sulfides, and pyrite. (Cooke and Simmons, 2000). The geochemistry of low-sulfidation epithermal deposits is characterized by anomalously high concentrations of Au, Ag, As, Sb, Hg, Zn, Pb, Se, and K.

Figure 6-6 is a schematic model of a low-sulfidation epithermal mineralizing system modified from White and Hedenquist (1995), Hedenquist et al. (2000), Cooke and Simmons (2000), and Sillitoe and Hedenquist (2003). The geological setting of the Sleeper project is somewhat more complex than the simplified model in the figure, but the overall geometry and association of features are similar.

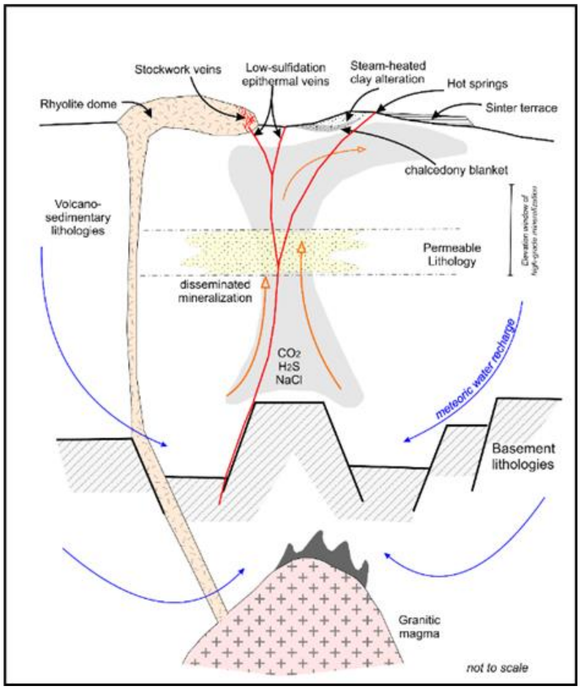

Figure 6-6: Schematic Model of Low-Sulfidation Epithermal Precious-Metal Systems

Schematic section showing geologic relationships in typical low-sulfidation epithermal precious-metal deposits. Meteoric water circulates to depths as deep as 5 kilometers through convection driven by heat from an underlying crystallizing magma (or from heated fluids accessed through crustal extension). At depths of 1-2 kilometers below the water table, within the upflow zone, maximum temperature-pressure gradients are close to boiling conditions. At shallower levels, the local hydraulic gradient may cause rising fluids to move laterally to form outflow zones. Separated vapor with CO_2 and H_2S may condense in the vadose zone to form steam-heated acidic waters.

Other low-sulfidation epithermal gold-silver deposits that formed in similar bimodal volcanic settings and exhibit similar characteristics include the Hollister, Buckskin-National, Jarbidge, Rosebud, Midas, Fire Creek, Sandman, and Mule Canyon deposits in northern Nevada, as well as the Grassy Mountain deposit in Oregon and the DeLamar district of Idaho. The deposits are linked spatially and temporally to near-source volcanic rocks erupted within a discrete period in the middle Miocene from approximately 17 and 15 Ma.

7.0 EXPLORATION

Exploration conducted by Paramount commenced in 2010 and has included soil sampling, geophysical surveys and drilling as summarized below.

7.1 PARAMOUNT GEOPHYSICAL SURVEYS 2010 - 2013

Paramount has completed three geophysical surveys since acquiring Sleeper in 2010 and contracted James Wright, J.L. Wright Geophysics Inc. to evaluate and interpret all of the Paramount and historical geophysical surveys. The following subsections summarize geophysical surveys conducted on the southern portion of the subject property between 2012 and 2015 for Paramount based on reports prepared by Mr. Wright who performed data processing and interpretation (Wright, 2012a; 2012b; 2015).

7.1.1 2012 GRAVITY 2012

In 2012, Paramount contracted Magee Geophysical Services LLC ("Magee") to conduct a gravity survey south of the historical Sleeper pit. Magee conducted a gravity survey over the southern portion of the property between March 28, 2012, and April 12, 2012. The objectives of the survey were to delineate structures, lithologies, and possible alteration related to gold mineralization (Wright, 2012a). Additionally, this survey aimed to fill in areas adjacent to a previous gravity study from 2005. Magee acquired a total of 1,019 gravity stations on a 100-meter grid, a 200-meter grid, and additional, widely spaced reconnaissance stations, which were added to the previous survey database. Relative gravity measurements were made with LaCoste & Romberg Model-G gravity meters. The gravity survey was tied to the gravity base at the Winnemucca Airport (DoD reference number 0474-1). Topographic surveying was performed with Trimble Real-Time Kinematic ("RTK") and Fast-Static GPS at the same time as gravity data acquisition. All gravity stations were surveyed for easting, northing, and elevation using the RTK GPS method or, where not possible, by Fast-Static method (Wright 2012) and tied to a GPS base station. Terrain corrections were calculated to 167 kilometers for each gravity station using various procedures for three radii around each station including 0-10 meters, 10-200 meters, and 2-167 kilometers. The gravity data were processed by Magee using the Xcelleration Gravity module of Oasis montaj (version 7.0) to Complete Bouguer Anomaly ("CBA") over a range of densities from 2.00 g/cc to 3.0 g/cc at steps of 0.05 g/cc.

Magee provided Mr. Wright with gravity data corrected to the CBA stage. Previous work by Mr. Wright at the Sleeper property indicated that a density of 2.35 g/cc was representative of the rock types in the survey area (Wright 2012a). Mr. Wright gridded the data with a kriging algorithm using a spacing of 50 meters with additional processing to produce regional, residual, and horizontal gradient grids. All four grids were contoured for import to MAPINFO and ARCGIS.

Mr. Wright concluded that the gravity data reflected three major north-south structures extending south from the Sleeper deposit for more than 30 kilometers. The structures bound a perched basin and horst block extending along the west side of the Slumbering Hills. The basin appeared to be detached from the Sleeper deposit by a major northwest structure, locally called the "Awakening Structure". Right lateral offset along the Awakening Structure accommodated basin and range extension and isolated the deposit area. North-South and northwest trending structures control mineralization at the Sleeper deposit with high-grade gold associated with their intersections. Mr. Wright indicated that three major north-south structures defined by the gravity survey should be considered as corridors of interest. Reconnaissance IP surveys were also recommended for certain areas within the project boundary to identify areas of elevated sulfide concentrations (Wright 2012a).

7.1.2 INDUCED POLARIZATION SURVEY 2012

Zonge International, Inc. ("Zonge") performed a gradient array induced polarization and resistivity ("IP/Res") survey on the southern extent of the property during July and August 2012. The purpose of the survey was to further clarify two areas of structural complexity identified as potential extensions of the Sleeper deposit during interpretation of the gravity survey conducted in March and April of 2012 by Mr. Wright. The gradient array IP/Res data were acquired along lines oriented N90° East using 50-meter receiver dipoles with 200-meter line spacing for approximately 62.7 line-kilometers of coverage. Zonge personnel used a Trimble PRO-XR GPS receiver that utilizes the integrated real-time DGPS beacon for position corrections. Each transmitting electrode consisted of three, four-foot diameter pits lined with aluminum foil and soaked with salt water. The electrode pits connected to the transmitter with 14-gauge wire. Measurements were made at 0.125 Hz. Each receiver spread consisted of six potential dipoles, comprising 300 meters of coverage per receiver set up (Zonge, 2012).

Measurement instrumentation consisted of Zonge model GPD-32^{II} multiple purpose receivers. The electric field was measured at the receiver site using non-polarizing ceramic porous-pot electrodes connected to the receiver with insulated 14-gauge wire. The signal source was a Zonge GGT-30 transmitter- a constant-current 30 kW transmitter controlled by an XMT-32 transmitter-controller. Power was provided by a Zonge AMG-30DL motor-generator equipped with an internal voltage regulator. Transmitter-receiver synchronization was maintained with identical crystal oscillators, synchronized before data acquisition. A minimum of three measurements were saved for each data point, with outlying values accounting for extraneous noise sources (such as lightening discharges and man-made electrical currents) removed from the data set. Zonge produced an average value for chargeability and resistivity for each data point.

Mr. Wright performed data processing and interpretation (Wright, 2012b). Mr. Wright processed the data with a kriging algorithm using a spacing of 50 meters with additional processing to produce regional, residual, and horizontal gradient grids. All four grids were contoured for import to MAPINFO and ARCGIS. Mr. Wright concluded that the north-south and northwest oriented structures interpreted from the 2012 gravity survey showed excellent correlation with the resistivity data. Mr. Wright also compared the resistivity and chargeability data to earlier IP and magnetic data. Good agreement was found between all the data sets. The data showed weak chargeability anomalies in both survey areas, relative to structures.

Mr. Wright proposed drilling six holes to further test the anomalies identified. The holes were proposed in areas with chargeability highs in geologic settings similar to that found at the Sleeper deposit and with interpreted structural connections to the deposit.

7.1.3 AIRBORNE MAGNETIC SURVEY 2015

Precision GeoSurveys of Vancouver, British Columbia performed an airborne magnetic survey of the southern portion of the Sleeper property on June 22-23, 2015. A total of 1,024 line-kilometers was surveyed on lines spaced 100 meters apart, and on an east-west orientation, with north-south tie lines every 1,000 meters. The survey lines were flown with a helicopter with a laser altimeter on board and the magnetometer attached to a boom extending from the front of the aircraft. The laser altimeter was used to measure the height of the magnetometer over the terrain (Wright, 2015).

The data was processed by Mr. Wright who merged the 2015 airborne magnetic survey with one flown in 1997 by Placer over the northern portion of the property, which included the Sleeper deposit. The surveys overlapped in the central portion of the property to allow level shifting of the 1997 survey to match that of the 2015 survey. Once the earlier survey data were corrected, Mr. Wright processed the combined data with a kriging algorithm at a spacing of 25 meters. The gridded field data was then reduced to the pole ("RTP") with a USGS algorithm. The RTP was further processed to produce a first vertical derivative ("VD"). All three of the processed datasets were then contoured as MAPINFO and ARCGIS files and used for interpretation (Wright, 2015).

Mr. Wright overlayed the interpreted magnetic data from the 2012 survey over the combined gravity data. Mr. Wright's interpretation included delineation of a large Jurassic intrusive body located south of the Sleeper deposit, which is bounded by two north-south structures to form a perched basin. A ridge to the west of the basin is composed of the Jurassic intrusion and is offset by a group of northwest oriented structures. Drilling by Paramount and earlier operators confirms that much of the southern portion of the subject property is underlain by the Jurassic intrusion and potentially mafic dikes.

7.2 PARAMOUNT DRILLING 2010 - 2013

Paramount commenced drilling at Sleeper in October of 2010 and continued through spring 2013. A total of 27,107 meters were drilled in 149 holes as summarized in Table 7-1. Approximately 67% of the holes and 45% of the meters were drilled with RC methods, including 65 shallow RC holes to sample historical waste dumps in the mine area. Nine holes in the waste dumps were drilled using sonic methods. Conventional wireline core drilling methods were used for 26% of the holes and 54% of the meters drilled by Paramount, including one hole started with RC and finished with a core tail. Paramount's drill hole collar locations are shown in Figure 7-1.

The initial drill campaign focused on two mine area zones (West Wood and Facilities areas) with the twin goals of validating the 2009 resource block model, and to demonstrate continuity/strike extension. Several holes were drilled to obtain samples for metallurgical testing.

Table 7-1. Paramount Drilling in 2010 - 2013

Year	Core Holes	Core Meters	RC Holes	RC Meters	RC+Core Tail Holes	RC+Core Tail Meters	Sonic Holes	Sonic Meters	Total Holes	Total Meters
2010	5	1,408.8	8	2,418.6	1	296.0			14	4,123.4

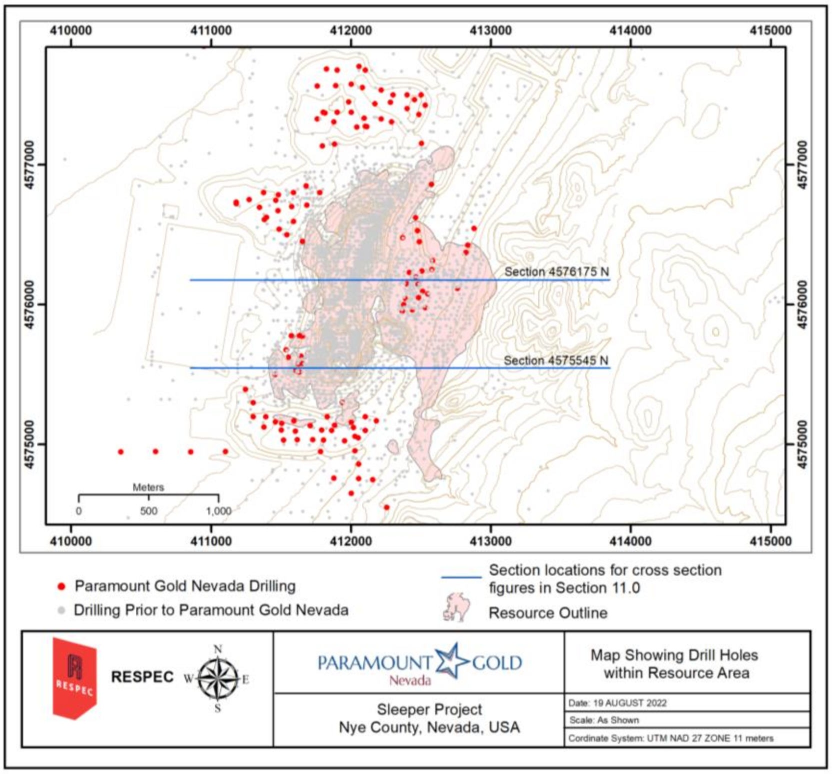
Figure 7-1: Map of Drill Holes Within the Sleeper Deposit

Commented [MN5]: Zoomed in Drill hole map with resource footprint



7.2.1 2010-2011 PARAMOUNT DRILL PROGRAM

During 2010 and 2011, Paramount drilled 15 core holes, 82 RC holes, nine sonic holes and one RC with core tail hole for a total of 13,151 meters. All drill hole locations were surveyed by hand-held GPS devices. The azimuth was marked on the ground to align the drill rig, whereas the angle was determined by the driller and checked by the site geologist when possible.

The RC drilling was carried out by DeLong Drilling and Envirotech Drilling, both of Winnemucca, Nevada. Some of the holes were drilled with a Schramm T685W truck-mounted rig. The equipment included 11.4-centimeter pipe and a face-return bit. The holes were drilled with a combination of a hammer bit at shallow depths and a tricone or rock bit once the hammer could no longer progress. The holes were drilled with water injection in the upper portion of the hole and with groundwater below the water table. The drill rig was equipped with a rotary splitter. The drillers were allowed to use bentonite to stabilize the holes when needed. The RC sample interval was 1.52 meters (5.0 feet). Each sample was collected in a cloth bag inside an 18.9-liter bucket to assure that adequate coarse and fine material was collected.

Each drill hole was surveyed down-hole by International Directional Services ("IDS") to measure deviation. RESPEC is unaware of the instrumentation, methods and procedures used by IDS.

The sonic drilling was conducted by Boart Longyear with an LS600 Sonic drill that utilized a combination of various sonic frequencies, rotation, core barrel, and borehole casing to collect samples in the unconsolidated mill tailings. The samples are retrieved directly from the core barrel and put into plastic bags the size of the core and labeled by the driller with the end depth of the sample interval.

The core drilling was carried out by Redcor Drilling of Winnemucca Nevada and American Drilling Corp. of Spokane, Washington. RESPEC is unaware of the rig type(s), methods and procedures used for the core drilling.

7.2.2 2012-2013 PARAMOUNT DRILL PROGRAM

Paramount drilled a total of 13,956 meters in 42 holes in 2012 and 2013 (Table 7-1). RESPEC's drilling database includes 24 core and 18 RC holes drilled by Paramount in 2012. It appears that similar down-hole survey methods and drilling methods and procedures from the 2011 program were used for the 2012 and 2013 RC and core holes, however RESPEC is unaware of the contractors and rig types used.

The Paramount drilling in 2010 through 2013 provided infill and added confidence to some of the historical drilling results within the "Facilities" and "West Wood" areas of the remaining, unmined portions of the Sleeper gold-silver deposit. No new mineralization was discovered with the Paramount drilling, but this drilling resulted in validation of earlier historical results and the core drilling provided samples for metallurgical testing as discussed in Section 10. Representative drill hole cross-sections showing the drilling results are provided in Section 11.0.

7.2.3 2021 PARAMOUNT DRILLING

After the effective date of the drilling database for the current mineral resources presented in Section 11.0, RESPEC was made aware of nine RC holes for more than 2,265 meters drilled in 2021 near the Sleeper open pit and the "Range Front" areas (Figure 7-2). Three of these holes were intended to be finished with core tails but were not completed to the planned RC depths and no core drilling was done. Assays, drill logs, and down-hole surveys have not been received for the 2021 drill holes and RESPEC has not verified the 2021 drill data and results.

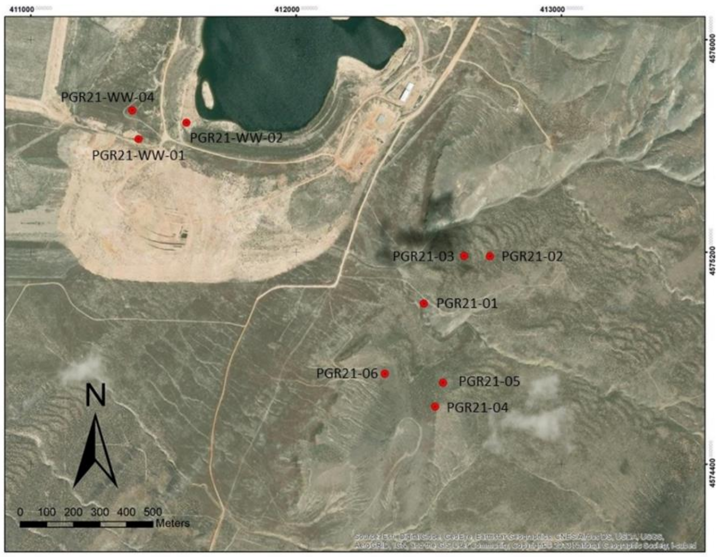


Figure 7-2: Map of 2021 Drill Collar Locations
(from Paramount, 2021)

7.3 PARAMOUNT EXPLORATION ASSESSMENT 2020

In 2020, Paramount conducted a target generation exercise for the Sleeper project with the assistance of RESPEC geologists. The exploration potential of the Sleeper project is discussed in Section 23.5.

7.4 HYDROGEOLOGY

The authors are not aware of any relevant hydrogeology data obtained by Paramount. RESPEC recommends that Paramount compile and evaluate any relevant historical hydrogeology data to the extent it may be available.

7.5 GEOTECHNICAL DATA

The authors are not aware of any relevant geotechnical data obtained by Paramount. RESPEC recommends that Paramount compile and evaluate any relevant historical geotechnical data to the extent it may be available.

8.0 SAMPLE PREPARATION, ANALYSIS, AND SECURITY

This section summarizes all information known to RESPEC relating to sample preparation, analysis, and security, and quality assurance/quality control ("QA/QC") procedures that pertain to the Sleeper project. The information has either been compiled by RESPEC from historical records or provided by Paramount. Much of this section has been extracted and modified from Gustin and Fleming (2004), Giroux et al. (2009) and Wilson et al. (2015, 2017).

The historical records of sample preparation, analysis, security, and QA/QC procedures summarized below are incomplete and have not been fully compiled and evaluated by Paramount. RESPEC recommends that Paramount fully compile and evaluate the existing historical information to the extent it is available.

8.1 HISTORICAL SAMPLE PREPARATION, ANALYSIS, QUALITY ASSURANCE/QUALITY CONTROL PROCEDURES AND HISTORICAL SAMPLE SECURITY

8.1.1 AMAX, PLACER DOME AND X-CAL 1983 - 2002

Available information was summarized by Gustin and Fleming (2004) who stated:

> "The authors do not have any documentation for sample preparation, bagging, security, and transportation practices used by Amax and Placer Dome. However, summary data sheets and summary reports prepared by these companies, their employees and geological consultants, and the analytical laboratories are available. The sampling done prior to X-Cal was handled by geological and engineering employees of and consultants to large, professional Canadian and American mining companies. It is not unreasonable to expect that these persons used sampling techniques in accordance with industry-accepted protocols. These organizations reportedly used accredited commercial laboratories in addition to in-house laboratories.
>
> X-Cal has established and maintained a strict regimen of quality control and quality assurance procedures in the handling, bagging, transportation, security, preparation, and analysis of exploration samples taken from the Sleeper Project. According to information made available to the authors, X-Cal used Bondar Clegg and Chemex for all of their assaying. Bondar Clegg is now wholly owned by Chemex, which is ISO 9002 registered and certified by KPMG in Canada and the U.S.A.
>
> X-Cal's sample handling, analysis and security procedures are described below. X-Cal's exploration samples were protected from contamination or disturbance from third parties by storage on plastic sheeting inside a guarded perimeter fence at the sample storage sites. No samples were collected by officers or directors of the company or any associate of the issuer. The samples were drilled, collected, transported, and processed by independent contractors.
>
> For samples submitted to Chemex, the procedures are described below. Chemex picked up the samples and transported them directly to its sample preparation facility in Elko, Nevada, using chain-of-custody identification and tracking procedures. Chemex prepared the samples

for assay and geochemical analysis. If the samples were wet, they were dried in low temperature ovens. Then, depending on the type of analysis requested, the samples were split, sieved, crushed, and pulverized. Finally, Chemex shipped the pulps to its laboratory in Vancouver, British Columbia for final chemical analysis, maintaining custody of the samples the entire time. The authors do not know procedures used for samples submitted to Bondar-Clegg. X-Cal has used a variety of quality control procedures in its verification of assay values reported by the Chemex. Two kinds of check assays were completed. Duplicate samples were selected by X-Cal personnel and analyzed by Chemex. In addition, assay "standard" samples, which have a verified known, measured content of minor and trace elements, were sent to Chemex along with regular samples in each given shipping batch. Where higher gold values were encountered in the drilling or the presence of visible gold is suspected by visual geologic logging and/or the panning-sluicing of samples, X-Cal requested a screen fire Metallic assay. All samples were sent to Chemex in Elko, Nevada. X-Cal's routine procedures involved submitting blanks and standards with each batch of samples. Duplicate samples were sent to American Assay Laboratories in Reno. The sampling and assaying procedures utilized by X-Cal on its Sleeper Project appear to have been professional and consistent with industry practice."

Bondar-Clegg and Chemex were commercial analytical laboratories independent from X-Cal. RESPEC is unaware of the specific laboratory certifications held by Bondar-Clegg and Chemex at the time of analysis of the X-Cal samples.

Records of laboratory sample preparation and analytical methods used by AMAX, Placer Dome, and X-Cal prior to 2003 are incomplete but to some extent exist in the files of Paramount. RESPEC recommends that Paramount fully compile and evaluate this data.

8.1.2 NEW SLEEPER GOLD 2004 - 2005

The methods and procedures used by the New Sleeper Gold joint venture for sample preparation, sample security and analysis of the 2004 and 2005 RC drilling samples have been summarized by Kornze et al. (2006) as follows:

"New Sleeper followed the regimen of quality control and quality assurance procedures in the handling, bagging, transportation, security, preparation, and analysis of exploration samples taken from the Sleeper Gold Property as defined in the written QA/QC protocol. New Sleeper used American Assay Laboratories and ALS Chemex for all of its assaying. Both laboratories are based in Reno.

New Sleeper's sample handling, analysis and security procedures followed generally accepted industry standards. Samples were protected from contamination or disturbance from third parties by storage on plastic sheeting inside a guarded perimeter fence and/or at the core logging and storage facility at Sleeper inside the perimeter fence. During the exploration drilling campaigns in 2004 and 2005 persons were present at the Sleeper site on a seven-day basis and at night the access gate was locked. This ensured security of samples. No samples were collected by directors of the company or any associate of the issuer. The samples were drilled, collected, transported, and processed by independent contractors.

Most drill samples were processed by American Assay Laboratories. American Assay picked up the samples from the core shed at Sleeper and transported them directly to its sample preparation facility in Sparks, Reno, Nevada, using chain-of-custody identification and tracking procedures. American Assay prepared the samples for assay and geochemical analysis. If the samples were wet, they were dried in low temperature ovens. Then, depending on the type of analysis requested, the samples were split, sieved, crushed, pulverized, and analyzed at Sparks. American Assay laboratories thus maintained custody of the samples the entire time. Finally, American Assay laboratories shipped the pulps back to Sleeper where they have been stored in secure steel containers.

New Sleeper used a variety of quality control procedures in its verification of assay values reported by American Assay Laboratories. Duplicate samples were collected from RC holes and included in each batch dispatched from the Sleeper Gold Property site. In addition, assay "standard" samples, which have a verified known, measured content of gold and silver, were sent to American Assay Laboratories along with regular samples in each given shipping batch. Standard samples were submitted with all drill sample consignments irrespective of drilling method. Generally, 1 in 20 samples was a "standard". Where higher gold values were encountered in the drilling or the presence of visible gold is suspected by visual geologic logging New Sleeper's protocol required a screen fire Metallic assay. Selected drill samples were also submitted to a third party for check assay following completion of the primary analysis by American Assay Laboratories. These samples representing approximately1 in 20 were in sent to ALS Chemex."

RESPEC is unaware of the laboratory sample preparation and analytical methods used by New Sleeper Gold. RESPEC believes that this information likely exists in the files maintained by Paramount and recommends that Paramount fully compile and evaluate this information to the extent it is available.

RESPEC is unaware of the actual QA/QC procedures used by New Sleeper Gold, or the results of analyses of QA/QC samples that may have been used by New Sleeper Gold. RESPEC believes significant QA/QC information from New Sleeper Gold has not been compiled or evaluated by Paramount. RESPEC recommends that Paramount fully compile and evaluate the New Sleeper Gold QA/QC procedures and results to the extent they are available.

8.1.3 X-CAL 2003 - 2007

According to Giroux et al. (2009), X-Cal's procedures for core and RC samples were as follows:

"American Assay Laboratories were scheduled to pick up the sample "cribs" near the end of a 10-day drilling shift. Predominantly one drill hole was placed in the shipping crib. If additional crib room is needed to ship a few samples from another drill hole, a plastic liner separates the two sample sets. This procedure helps the lab personnel sort the core or RCD samples after delivery to the Sparks, Nevada prep facilities and prevents co-mingling of drill holes located in different target areas. Duplicate RCD samples were collected from every drill hole on 150 feet increments. Example: drill hole FAC-07-55, sample interval 145-150 feet would have a duplicate split collected at the wet splitter and labeled 145-150 D. The duplicate RCD samples were temporarily stored on plastic liners near at the geology office. The duplicate samples for

> each individual drill hole once air-dried were placed in larger shipping bags labeled with drill hole numbers and intervals.
>
> The duplicate samples were stored at Sleeper mine site until a shipment quantity "batch" would be ready for transport. The samples would be hand delivered by Sleeper personnel to the ALS Chemex's prep facilities located in Winnemucca, Nevada. Assay submittal sheets and standards accompanied the samples and copies of the submittals were retained by X-Cal for archive.
>
> Duplicate samples were collected at the RCD rig every 150 feet (45 meters) and identified by a letter "D" following the footage designation. Duplicate samples of specific core intervals were selected from sample rejects after the principle [sic] lab preparation and assays were completed. Commercial standards of various gold concentrations (pre-packaged pulps) were introduced into the analytical lab's sample stream at the pulp stage."

American Assay Laboratories ("AAL") and ALS Chemex ("Chemex" or "ALS") were commercial analytical laboratories independent of X-Cal. RESPEC is unaware of the specific laboratory certifications held by AAL and Chemex during 2003 through 2007.

During 2003 at Chemex, gold was determined by fire-assay fusion of a 50-gram aliquot followed by an atomic adsorption ("AA") finish. In some cases, gold was also determined by fire-assay fusion of a 50-gram aliquot followed by a gravimetric finish. Silver was determined by AA and inductively coupled plasma optical-emission spectrometry ("ICP-OES" or "ICP") after a 4-acid digestion. In some cases, silver was determined by fire-assay fusion followed by a gravimetric finish.

At AAL during 2003, gold was determined by fire-assay fusion followed by a gravimetric finish. Silver was determined by AA after a 2-acid digestion and in some cases by fire-assay fusion with a gravimetric finish.

The same analytical methods were used at ALS and AAL for drill samples analyzed during 2004 -2006. In addition, some samples were analyzed for gold by both labs using a 50-gram fire-assay fusion followed by an ICP finish. Some samples were also analyzed at AAL using a "metallic screen" fire-assay fusion procedure. In 2006, ALS determined silver by ICP-OES after an aqua regia digestion and gold was determined by fire-assay fusion followed by an ICP finish. Beginning in 2007 and continuing in 2008, gold and silver were determined at AAL and ALS in some cases using a 30-gram fire-assay fusion with either an AA or gravimetric finish.

The X-Cal QA/QC program in 2007 was described by Giroux et al. (2009) as follows:

> "The assay quality control program used during 2007 was industry standard and included collection of field duplicate samples, insertion of reference samples (standards), and regular submission of samples to a second laboratory for check analyses. The principal laboratory was American Assay Laboratories (AAL) in Reno, Nevada, and the check laboratory was ALS-Chemex (ALS) in Reno, Nevada Prior to submitting samples to AAL, X-Cal had a stipulation protocol that drill samples submitted for assay would require an automatic check assay by AAL if gold values reported were greater than 3 grams and or silver values were greater than 60

grams. In addition, drill intervals that were inspected by the supervisory geologist and visually contained geologic features that accompany higher-grade mineralization, including but not limited to banded veins, dark sulphide bearing breccias, antimony sulphides or visible gold were reported to the lab prior to assay analysis. The principle [sic] lab preps the indicated higher-grade zone. Between each of the individual samples that have been highlighted by the supervisory geologist, 5 feet for RCD and 2 ½ feet for core, a barren silica sand flush was used to clean the grinding equipment.

A total of 565 samples were assayed as check samples (565 samples to AAL and 565 duplicates to ALS). The standards inserted into the sample stream totaled 359. Results of the assay quality control program show generally acceptable gold assaying. For future drilling programs, additional check assaying is recommended. Field duplicates were collected while drilling for the reverse circulation drill holes. Core duplicates were collected from processed core rejects that were returned to the Sleeper mine site by the principle [sic] laboratory (AAL) and then the same reject was sent to the secondary lab (ALS) for check analysis."

According to historical records reviewed by RESPEC, X-Cal also inserted coarse blanks into the 2003-2007 drill sample stream. The blanks were reportedly created in-house, but the origin of the blank materials and other details are not known.

RESPEC's evaluation of the X-Cal QA/QC information as summarized in Section 8.3.

8.1.4 EVOLVING GOLD 2009

Evolving Gold's drilling, sample preparation and laboratory analytical methods have not been compiled by Paramount. RESPEC is unaware of the methods and procedures used and recommends that Paramount fully compile and evaluate the Evolving Gold drill data for consideration in future studies of the Sleeper project.

8.1.5 MONTEZUMA MINES 2011 - 2012

Montezuma Mines' drilling, sample preparation and laboratory analytical methods have not been compiled by Paramount. RESPEC is unaware of the methods and procedures used and recommends that Paramount fully compile and evaluate the Montezuma Mines drill data for consideration in future studies of the Sleeper project.

8.2 PARAMOUNT SAMPLE PREPARATION, ANALYSES, SAMPLE SECURITY AND QUALITY ASSURANCE/QUALITY CONTROL PROCEDURES

Samples from Paramount's drilling in 2010-2013 were transported by drill contractors from drill sites to the Paramount shop at the Sleeper site facilities outside of Winnemucca, Nevada. Drill core was placed in core boxes and marked with wooden blocks, in feet, by the drilling contractor. The core was transported to the shop logging facility at site daily to have the wooden blocks converted to meters. At the logging facility, each box was photographed and placed on a core logging table or a pallet. The core was then logged by a Paramount geologist who recorded lithological, alteration, mineralization, and structural information, including the angle of intersection of faults with the core, fault lineations, fractures, veins, and bedding. The entire length of core was then prepared for sampling.

Sample intervals were based on the geological logs in an effort to separate different lithologies and styles of mineralization and alteration. Sample length generally did not exceed 1.52 meters (5.0 feet) and, where possible, correlates to the drilling runs. If any significant veins, veinlets, healed breccias, or other potentially mineralized planar features were present, the geologist marked a line down the length of the core where the core should be sawed or split to ensure a representative sample was taken by the sampler. After logging was completed, sample intervals were marked and assigned a unique sample identification (sample tag), with the sample tag stapled inside of the box at the end of each sample interval. A duplicate sample tag for each interval was placed inside the sample bag, and the sample number was recorded in the sample tag booklet. Sample numbers were numeric and did not identify the drill hole, depth, or any other indication of sample location.

The core boxes were then moved to the sampling station where a technician cut competent core in half with a diamond-blade core saw, while highly broken core was split by hand directly from the box using a brush and spoon in an effort to take a representative half-core sample. One half of the core was placed into a cloth sample bag labeled with the sample number. The other half was placed back into the core box for future reference. The responsible technician filled out a core cutting/splitting form recording the sample number, the starting and ending footage of the sample interval, and the date. The sample bags were tied off and stored in the secure shop facility until the sample batch was ready to be shipped.

When the core samples were prepared for shipment, they were laid out in order (including quality assurance/quality control samples) at the Paramount logging facility at site. A complete sample inventory was filled out and maintained. Drill core sample bags were placed into rice bags, and each rice bag was sealed with a numbered security seal. Only samples from a single drill hole were included in a shipment. A sample submittal form was prepared with the shipment number, security seal numbers, the sample numbers, the type of analyses requested, and a list of samples to be duplicated. A hard copy of the submittal form was included with the sample shipment and an electronic copy was emailed to the lab.

No core duplicates were collected. A coarse reject (or preparation) duplicate for every 20 samples, and a pulp-duplicate analysis of every 20th pulp was requested from the laboratory. Additionally, one sample in every batch of 20 samples was to be quartered and both quarters submitted to the lab as duplicates with different sample numbers. Control blanks and reference standards accompanied each 20-sample batch to the laboratory. The labs were instructed to run samples in numerical sequence to ensure that field QA/QC samples were assayed in each batch.

RC samples were collected in a cloth bag inside a five-gallon bucket to assure that adequate coarse and fine material was collected. All sample bags were labeled with a unique sample number only with careful record kept with the corresponding depth/interval/ hole number. All samples were tied and put into sample crates, which were then picked up from the drill site or from behind the locked gates of the mine site by ALS. The date and the number of samples transported were recorded on a sample handling form. The samples were arranged in a manner to ensure that all samples, blanks, and standards were accounted for, and were photographed prior to shipment for analysis.

RC rig-duplicate samples were collected at the drill rig as described in Section 7.2. For RC sampling one sample in every batch of 20 samples was quartered and both quarters submitted to the lab as duplicates with different sample numbers. Control blanks (barren material) and certified reference materials ("CRMs") accompanied each 20-sample batch to the laboratory. The duplicates were delivered to Inspectorate, a secondary laboratory, as a check on ALS the primary laboratory. The labs were instructed to run samples in sample number numerical sequence to ensure that standard reference samples and coarse blanks were assayed in order in each batch.

During the 2010-2013 drilling programs, commercially prepared CRMs obtained from MEG, and RockLabs, and were inserted into the sample sequence for the purpose of QA/QC. To meet Paramount's QA/QC protocols, the standards needed to assay within three standard deviations of the recommended gold value furnished from MEG, RockLabs, and CDN. Two of the CRMs have certified silver values as well. If any samples assayed outside the three standard deviation limits, the sample previous to and after the failed sample were examined for accuracy and for cohesiveness with the geology and mineralization. Any failures and surrounding samples that were thought out of the ordinary after this examination were re-assayed.

The blank materials used by Paramount are shown in Table 8-1.

Table 8-1. Paramount Blank Materials for 2010-2013

Blank ID	Certified Value	Type	Origin
AuBlank40	<0.002 ppm	coarse	MEG Labs
MEG-Blank.11.01	<0.005 ppm	pulp	MEG Labs
Blank	<0.005 ppm	coarse	commercial crushed white marble

Sonic drilling samples were taken directly from the drill pipe and put into plastic bags the size of the core and labeled by the contractor with the "ending" footage and an arrow. The samples were picked up from site, delivered to the shop facility and placed on the core logging tables in order. The geologist logged the samples and measured off meters. Each one-meter sample was then placed in one or two 45.7 by 61-centimeter plastic bags and closed for shipping. The samples were placed in samples bins and transported to McClelland Laboratories ("McClelland") by DeLong Construction and Drilling Company in a large transport truck. Lids were nailed on the sample bins to keep them secure. The samples were delivered to the laboratory the same day they were picked up from Sleeper.

The samples were logged into McClelland and adequate material for analysis was split from each one-meter sample. The samples were coarsely crushed at McClelland and then delivered to ALS for determination of gold by fire-assay fusion with an AA finish and silver by ICP analysis. CRMs were inserted every 20th sample.

ALS crushed the samples to 75% passing a six-millimeter mesh and then split off 250-gram subsamples for pulverization to 85% at -<75 microns (200 mesh). Cleaner sand was run through the crusher every five samples or at any color change in the sample noticed by ALS technicians. Cleaner sand was pulverized between every sample in the pulverizing step. ALS was independent from Paramount and maintained an ISO 9001:2008 accreditation for quality management and ISO/IEC17025:2005 accreditation for gold assay methods.

In 2011 and 2012, silver was analyzed at ALS by ICP following a 3-acid digestion, and, in some cases, by 50-gram fire-assay fusion with a gravimetric finish. Gold was determined at ALS by both 30-gram and 50-gram fire-assay fusion with either an AA or gravimetric finish.

During 2011 and 2012, samples were also analyzed at Inspectorate in Sparks, Nevada. Silver was determined by either AA after a 4-acid digestion, or by ICP following an aqua regia digestion. Gold was determined by 30-gram and 50-gram fire-assay fusion with either an AA or gravimetric finish. Inspectorate was a commercial analytical laboratory independent from Paramount. RESPEC is unaware of the certifications held by Inspectorate in 2011 and 2012.

During 2013, all drill samples were analyzed at ALS. Gold was determined by 30-gram or 50-gram fire-assay fusion with either an AA or a gravimetric finish. Silver was determined by AA, ICP and fire-assay fusion with a gravimetric finish.

Pulps were split to separate a 30-gram aliquot for determining gold by fire assay with AA finish (ALS code Au-AA23). A separate five-gram aliquot was used for ICP-AES determination of silver and 32 major, minor, and trace elements following a four-acid digestion (ALS code ME-ICP61). Further aliquots were taken from the same pulp for fire assay with gravimetric finish (ALS code Au-GRA21) if the original gold assay exceeded the 10.0 g Au/t upper limit of detection. Samples that assayed greater than 100 g Ag/t were reanalyzed using a 10-gram aliquot with a four-acid digestion for silver and an AA finish (ALS code AG-OG62). Samples that assayed greater than 1,500 g Ag/t were reanalyzed using a 30-gram fire assay with a gravimetric finish (ALS code Ag-GRA21).

Paramount compiled an electronic database containing all historical and 2010-2013 drilling information. This database is maintained using SQL software and is housed by an off-site remote server that is controlled by a third-party database expert. All database inquiries and data requests are routed through this third-party expert. All data are controlled by Paramount's designated data manager and this third-party expert in order to prevent any unauthorized changes to the Paramount database. Paramount has established QA/QC protocols for data management, verification, validation, and data screening. These protocols consist of primary and secondary checks on electronic entry of field data, drill hole data, sample information, assays, and geochemistry. All information is verified and cross checked by Paramount and the third-party database expert to ensure accuracy.

8.3 QUALITY ASSURANCE/QUALITY CONTROL RESULTS

RESPEC has compiled and evaluated QA/QC results from X-Cal's 2003 to 2007 and Paramount's 2010 to 2013 drilling programs that have been found as of the date of this report. Efforts are ongoing to uncover additional data where possible. Analyses of certified reference materials ("CRMs" or "standards"), blanks, field duplicates, preparation, and pulp duplicates have been identified, and where possible, compiled and discussed in this section.

The CRMs, blanks, and field duplicates were inserted into the primary drill sample streams that were submitted to the primary lab, and the preparation and pulp duplicates were created at the primary lab. All of the QA/QC samples discussed herein were analyzed by the primary lab, with the exception of X-Cal's core preparation duplicates.

The QA/QC sample types are described as follows.

CRMs. CRMs are used in mineral exploration are usually powders comprised of rock-forming minerals that include metal(s) of interest in known concentrations, and they are used to assess analytical accuracy. CRMs analyses are evaluated using criteria for passing or failing. CRMs are usually obtained from commercial suppliers, and these suppliers provide specifications that include the average of many analyses of the CRMs by multiple labs, which is referred to as the certified value, as well as the standard deviation of the analyses from which the certified value is determined.

A typical criterion for accepting the analyses of CRMs in the mineral industry is that they should fall within a range determined by the certified (or "expected") value ± three standard deviations.

Blanks. Blanks are samples determined to have metal concentrations less than the applicable detection limits of the metals of interest. There are two types of blanks used in the minerals industry, coarse blanks and analytical (or pulp) blanks, both of which are used to monitor for potential laboratory contamination. Analytical blanks are pulps of barren materials, and as such, can only identify contamination at the analytical stage. Since analytical contamination is rare, these blanks are of limited usefulness. Coarse blanks must be of sufficient particle size to require them to be subjected to all sample preparation stages that are require for the associated primary drill samples. Coarse blanks are used to provide information relevant as to possible laboratory contamination during sample preparation (crushing and pulverizing). The source of the cross contamination, if present, is usually attributable to the sample(s) immediately preceding the contaminated blank. Blanks yielding values over five times the detection limit are considered to be failures.

Pulp Duplicates (or Replicate Analyses). Pulp Duplicates are second analyses of the original pulps that are often performed routinely by the primary analytical laboratory. These duplicates can be used to evaluate the precision of the subsampling of the pulp and of the analysis.

Preparation Duplicates. Preparation duplicates are new pulps prepared from secondary splits of the original coarse rejects created during the first crushing and splitting stage of the primary drill samples. These samples provide information about the subsampling variance introduced during the sample preparation process, as well as to assess the representativity of the sample splitting of the coarse rejects at the laboratory.

Field Duplicates. Field (or rig) duplicates are secondary splits of drill core or RC cuttings taken at the drill rig, or in the case of core, later from the core box at the core logging and sampling site. Field duplicates can be useful in the identification of problems in sample splitting, as well as to assess sampling variance experienced in the field.

The analytical labs and analytical techniques used for the primary drill samples and QA/QC samples, as well as the reported QA/QC insertion rates and other details, are discussed in 8.2 and Sections 8.3.2.

Table 8-2 summarizes the quantities of QA/QC data RESPEC has been able to compile as of the effective date of this report for the X-Cal and Paramount drilling, which are generally less than indicated by the reported insertion rates.

Table 8-2. Summary Counts of Sleeper QA/QC Analyses

	2003-2007		2011-2013	
QA/QC Type	Au	Ag	Au	Ag
Standard (CRM):				
Number in Use	N/A	N/A	12	6
Number of Analyses	N/A	N/A	387	16
Number of Failures	N/A	N/A	13	0
Duplicate:				
Field Duplicate	822	875	200	199
Preparation Duplicate	642	309	0	0
Pulp Duplicate	1610	2451	0	42
Lab Preparation Duplicate	0	64	0	6
Lab Pulp Duplicate	162	11	0	0
Blank:				
Pulp Blank	0	0	56	0
Coarse Blank	42	35	231	230
Lab Prep Blanks	0	0	8	10
Drill hole Samples:	51325	44980	10134	10137
Total Insertion Percent:	5.00	4.93	8.11	4.42

Table 8-3 shows summary data for the field duplicate pairs for both X-Cal and Paramount's 2011 to 2013 (RESPEC found no QA/QC data from Paramount's five-hole drilling program in 2010).

Table 8-3: Summary of Results for X-Cal Historical and Paramount Field Duplicates

Laboratory	Duplicate Type	Drill Type(s)	Element	Period	Counts			RMA Regression	Averages as Percent	
					All	Used	Outliers	y = Duplicate x = Original	Rel Pct Diff	Abs Rel Pct Diff
ALS Minerals Inspectorate ACME Labs	Field Dup	R/C	Au	2003-2007	822	757	65	Y = 1.0047x + 0.0027	3.56	31.12

8.3.1 X-CAL HISTORICAL QUALITY ASSURANCE/QUALITY RESULTS

8.3.1.1 CRMS 2003 -2007

Although RESPEC confirmed that X-Cal's 2003 to 2007 drilling program included the use of CRMs, the documentation of the CRMs has not been found, so the CRMs could not be evaluated.

8.3.1.2 BLANKS 2003 - 2007

Table 8-4 summarizes the blanks inserted by X-Cal in 2003 through 2007.

Table 8-4. Summary of Results for Blanks 2003 - 2013

Blank ID	Drill Program	Elem	Counts		Maximum	Dates of Analyses	
			All	Above Warn	(ppm)	Start	End
Coarse Blank	2003-07	Au	38	4	0.1710	23/Mar/04	20/Jun/05
Coarse Blank	2003-07	Ag	35	1	5.3000	23/Mar/04	20/Jun/05

A total of 38 coarse blanks were found from the X-Cal drilling and these blanks were analyzed for both gold and 35 for silver with detection limits of 0.005 ppm and 0.2 ppm, respectively. This undoubtably represents a small subset of the blanks actually analyzed, the bulk of which were either not described in enough detail to determine the type of blank or not reported in the data evaluated by RESPEC.

Four failures for gold and a single failure for silver were identified using failure limits of five times the detection limit for gold and twice the detection limit for silver. Silver was handled differently than the normal five times detection limit since the detection limit was relatively high. Table 8-5 shows the blank failures:

Table 8-5. X-Cal **Blank Failures and Preceding Samples 2003-2007**

Blank	Certificate	Elem	Method	Preceding		Blank		5x Det Limit (ppm)
				Sample	Value (ppm)	Sample	Value (ppm)	
Blank	SP065348	Au	ICP	27805	1.2260	27806	0.0280	0.025
Blank	SP065582	Au	F50/ICP	28127	1.6200	28128	0.0500	0.025
Blank	SP065732	Au	F50/ICP	28248	0.6720	28249	0.0300	0.025
Blank	SP068824	Au	F50/ICP	WW39-05 34018	0.0110	WW39-05 34019	0.1710	0.025
Blank	SP068894	Ag	AA	NS-01-05 30854	0.6000	NS-01-05 30855	5.3000	1.000

Three of the four blank failures are preceded by samples with higher grade gold or silver values Figure 8-1. This indicates there likely to have been intermittent issues with the crushing circuit at AAL between

May 2004 and April 2005 that led to cross-contamination. The other failure may have been due to a mislabeled sample.

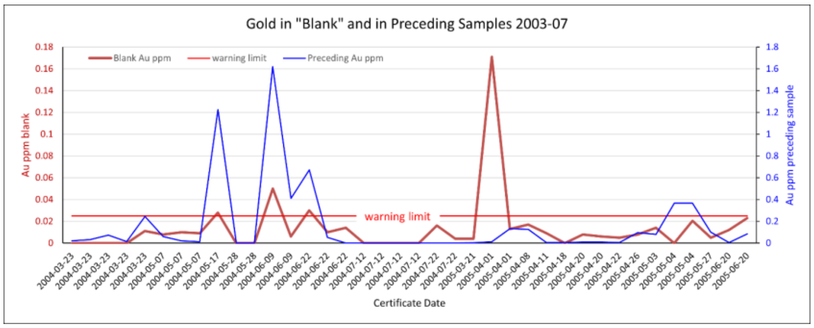

Figure 8-1: X-Cal Gold in Blanks and Preceding Samples 2003-2007

8.3.1.3 DUPLICATES 2003 - 2007

RESPEC evaluated the various types of duplicate pairs through scatterplots showing RMA regressions, quantile/quantile plots, relative-percent difference ("RPD") plots, and plots of the absolute value of the RPD. Two types of RPD plots were used, the maximum of the pair and mean of the pair plots, with the relative differences calculated as follows:

RPD(max) = 100 x ((Duplicate – Original))/(Lesser of (Duplicate, Original))

The relative percent difference of the mean of the pair is expressed as follows:

RPD(mean) = 100 x ((Duplicate – Original))/(Mean of (Duplicate ,Original))

The RPD(max) method yields higher magnitude relative differences as compared to the RPD(mean) calculation.

Outlier pairs were discarded from scatterplots based on visual analysis, while pairs with absolute values greater than 2000% were removed from the RPD plots. While the outliers were removed to avoid statistical anomalies, many are nonetheless relevant and should be considered as part of an overall evaluation. Only pairs with misidentified sample numbers or sample origins are irrelevant. The causes of the extreme variations therefore require further review.

Pulp Duplicates. Pulp duplicates have been found but remain in the process of compilation.

Preparation Duplicates. Giroux et al. (2009) noted that core duplicates were collected from core coarse rejects that were returned by AAL to the Sleeper mine site. Selected samples of the coarse rejects were then sent to ALS for sample preparation and analysis. These samples were therefore preparation duplicates of core drill samples, although instead of having these prepped and analyzed by the primary lab (AAL), as RESPEC recommends, they were sent to ALS. Figure 8-2 shows an RPD for the core preparation duplicates for gold.

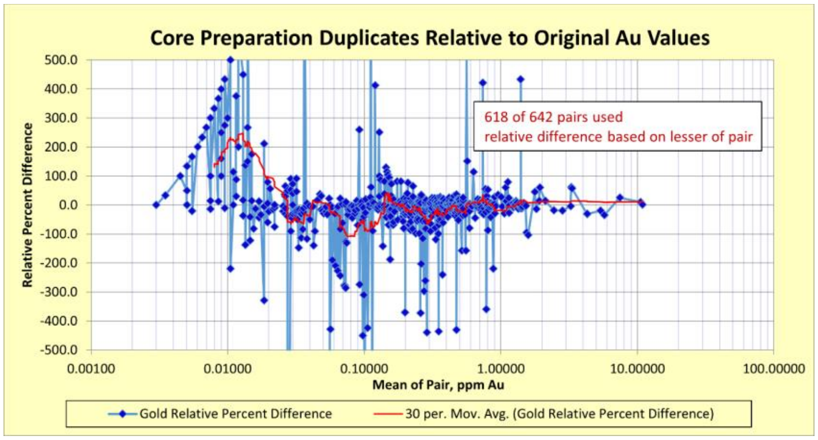

Figure 8-2: X-Cal Gold Core Preparation Duplicates, Relative Differences 2003-2007

At relevant grades (>~0.1 g Au/t), the majority of the duplicate pairs lie between the RPD limits of +50% to -50%, most within +/-25% limits. The small percentage of pairs with much higher RPDs indicate significantly higher variability between the original sample gold analysis the duplicate analysis. No bias is evident in the data, although the higher-variability pairs cause the red moving-average line to deflect from 0% RPD to varying extents (data that have RPDs that average ~0% exhibit no bias).

Figure 8-5 is an RPD chart that plots the absolute value ("AV") of the RPD for each gold sample pair. This type of chart is used to show the magnitude of variability in a duplicate dataset.

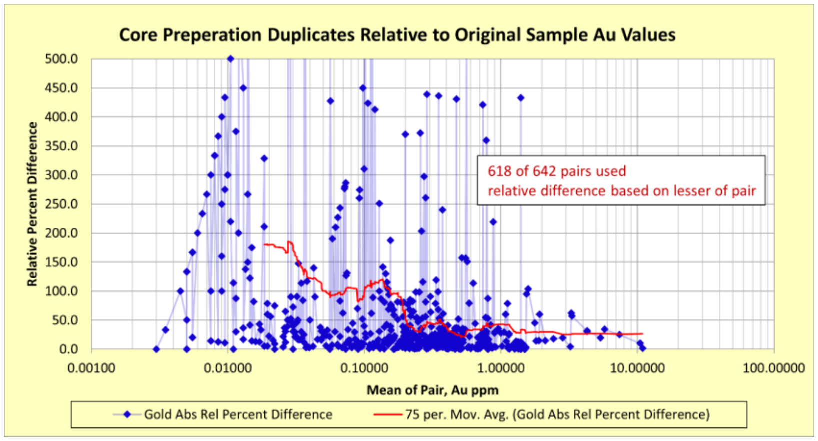

Figure 8-3: X-Cal Gold Core Preparation Duplicates, Relative Differences 2003-2007

Field Duplicates. Figure 8-4 shows the RPDs of the X-Cal RC gold field duplicates.

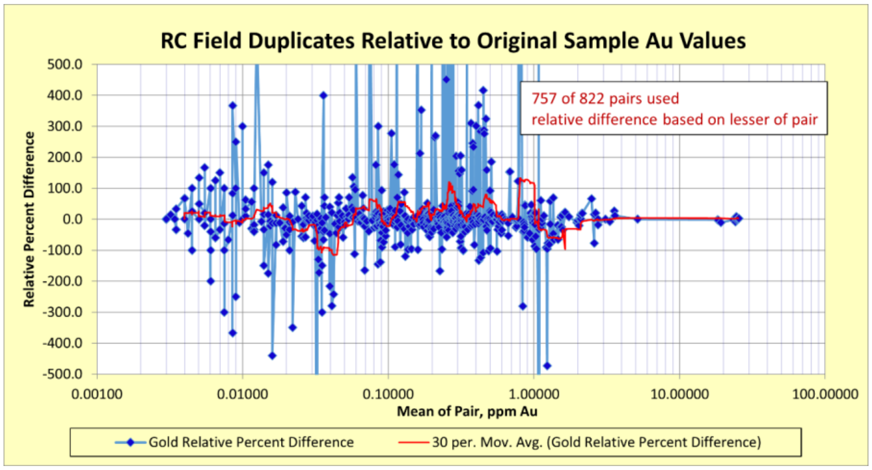

Figure 8-4: X-Cal Gold RC Field Duplicates, Relative Differences 2003-2007

While the moving-average line in this dataset is overly influenced by extreme outliers, which limits its usefulness, statistical analyses of the dataset indicate there is a high bias in the gold analyses of the duplicates relative to the original sample assays. However, this bias is not present if the 16% of the sample pairs are removed that have AVs of the RPDs exceeding 100%, which means the high bias is entirely caused by the 16% of the pairs that have very high variability. The silver RC field duplicates show similar relationships, which is expected as both gold and silver are reported to occur primarily within electrum.

The average AV of the RPDs is 24% for sample pairs with AVs less than or equal to 100%, which is to say most of the sample pairs within this AV range are less than 50%, a level not unusual for field duplicates. This issue is with the number of pairs having AVs of the RPDs in excess of 100% (high variability), as well as these pairs tending to have duplicates with higher grades, on average, than the original samples. It is important to note that high variability at low-grade ranges is expected, due to lower precision in analyses at these grades and higher RPDs because percentage differentials are exaggerated for low values.

Absent sample mix-ups and other data related problems, the most likely cause of the greater than 100% AV of the RPDs that cause the high bias in the RC duplicate samples is unrepresentative splitting of the RC sample cuttings at the drill rig. The best-case scenario would be that this unrepresentative splitting occurred only during the sampling of drill intervals for which the second (duplicate) was collected. This could happen if the RC sampling protocols were different for the duplicate sampling intervals versus drill intervals that only original samples were collected, which while poor practice that yields useless data, RESPEC has seen at certain projects over the years. Absent this scenario, the routine RC sample splitting was not representative approximately 15% to 20% of the time.

To illustrate the degree of variability in the X-Cal field duplicates, Figure 8-5 shows the absolute values of the relative percent differences (based on RPD(max)) for the RC duplicate pairs. Note that the pairs exceeding AVs of the RPDs of 500% are indicated by the blue lines without points at their apices, which are truncated at the top of the plot.

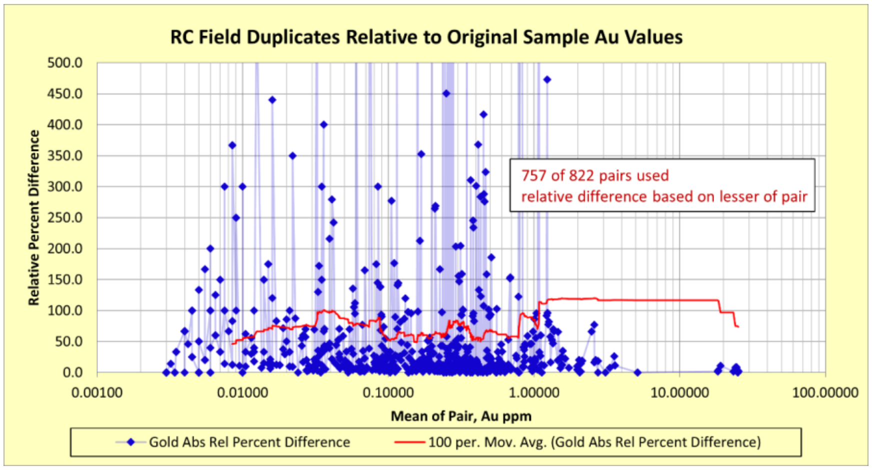

Figure 8-5: X-Cal Gold RC Field Duplicates, Absolute Values of the Relative Differences 2003-2007

Field duplicates incorporate the inherent variability of the mineralization as well as the variability imparted by all other subsampling stages, including: (i) subsampling of the coarse rejects to obtain material to be pulverized; (ii) subsampling the pulverized material to obtain an assay pulp; (iii) subsampling of the assay pulp to obtain an aliquot for analysis, and (iv) the variability in the sample analyses. All variability imparted prior to the splitting of field duplicates is incorporated into the preparation duplicates.

In the case of the Sleeper duplicate datasets, approximately half of the variability seen in the RC field duplicates is evident in the core preparation duplicates. While the core preparation duplicates were not assayed at the same lab as the RC field duplicates, which is not ideal, the lack of bias in the core duplicates suggests that comparing the two datasets to evaluate variability has value.

Similar to the RC field duplicates, the core preparation duplicates are characterized by very high variability pairs at relevant gold grades, but the proportion of these pairs is less than that in the RC dataset, and the core high variability pairs are not causing bias. This supports the conclusion that there may have been RC splitting issues at the rig in the X-Cal 2003 to 2007 drilling programs.

The very highly variable pairs should be investigated to be sure of the validity of the pairs, and if valid, possible causes/nature of the variability (e.g., are they more numerous in certain time periods or in certain locations).

High variability pairs are expected due to the nugget effect imparted by the well documented occurrence of gold and silver in electrum in the Sleeper deposit. Irrespective of possible splitting issues, this inherent variability adds risk to the estimation of resources and must therefore be carefully considered in the choice of estimation methodologies.

8.3.2 PARAMOUNT QUALITY ASSURANCE/QUALITY CONTROL RESULTS

8.3.2.1 CRMS 2010 -2013

Paramount used four CRMs obtained from MEG of Reno, Nevada and eight from RockLabs of Perth, Western Australia. All 12 CRMs were certified for gold, with some listing silver values, but these values were not certified. Based on available data compiled by RESPEC, the CRM insertion rate for the 2010-2013 drilling was about 4% for gold and less than 1% for silver. The lower silver insertion numbers were because not all the CRMs had listed values for silver and not every drill sample was analyzed for silver. Table 8-6 summarizes the CRMs used by Paramount that were compiled by RESPEC.

Table 8-6: CRMs used by Paramount

Standard ID	Drill Years	Insertion Count	Certified Au ppm	Au Std Dev ppm	Listed Ag ppm

RESPEC identified three high failures and ten low failures in the ALS analyses for gold that would be subject to further review. Three of the four CRMs from MEG had slight negative biases, as did five out of eight from RockLabs. Three CRM pulps listed on three certificates from this time frame were sent to Inspectorate in Reno, Nevada. Because so few of the samples were sent to Inspectorate, and the gold detection limits were the same, the two labs were evaluated together. Results for the CRM gold analysis are summarized in Table 8-7, and the failures are detailed in Table 8-8.

Table 8-7. Summary of Sleeper Gold Results for Certified Reference Materials 2010-2013

SN16	PGC-11-011	8.367	Low	7.716	7.620	613501	WN11164001

Two of the failures were from certificate RE11131983. That certificate had four CRMs and three blanks, all but the two passing. One of the failures (sample 616935) is likely to have been a mislabeled sample, as the MEG S107006X standard is in that range and was in use at that time. Four of the failures were very close to the failure limit, and with the negative bias, these are more the result of the bias than failures. Also, it is important to note that the CRMs were analyzed by ALS using AA fire assay finish as compared to the gravimetric methods used in the standard.

Figure 8-6 shows the control chart for the CRM MEG-Au.09.02, which shows the single low side failure. A consistent low bias in the ALS analyses of this CRM is also evident. The apparent failure, adjusted for this bias, is not actually a failure.

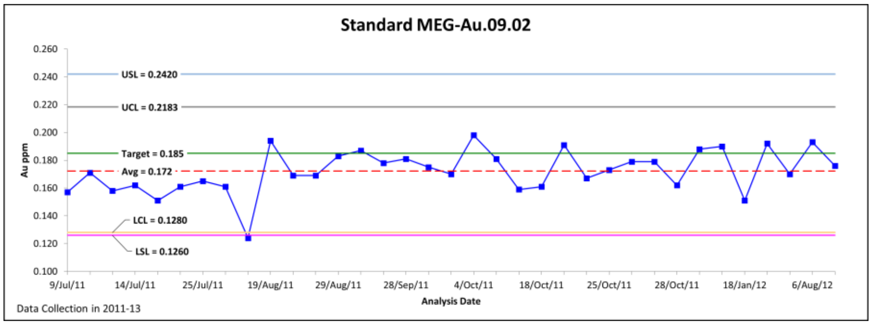

Figure 8-6. Gold Control Chart for MEG-Au.09.02

Explanation for Figure 8-6		
Items Obtained from Certificate for CRM		
USL	Upper Specification Limit	Target + 3 Std Dev (CRM)
Target	Expected Value (CRM)	
LSL	Lower Specification Limit	Target - 3 Std Dev (CRM)
Items Calculated using Paramount Data		
UCL	Upper Control Limit	Avg + 3 Std Dev (Population)
Avg	Mean Value (Population)	
LCL	Lower Control Limit	Avg - 3 Std Dev (Population)

For silver, only six of the CRMs had a listed, uncertified value. All silver analyses were run at ALS using a three-acid digestion with an ICP finish and a detection limit of less than 0.5 ppm. The sixteen CRM analyses performed at Inspectorate for silver were run with an aqua regia digestion and an AA finish. To deal with the listed values not having a standard deviation, the LCL/UCL control limits of the sample population were used to evaluate the silver CRMs. The following table shows the details, with no failures for silver in the 2011-2013 drill program. The low-side bias on three of the CRMs (MEG S107006X, MEG S107010X, and SN16) is most likely a difference in analytical methods used.

Table 8-9. Summary of Sleeper Silver Results for Certified Reference Materials, 2010-2013

Standard ID	Grades in Ag ppm				Count	Dates Used		Failure Counts		Bias pct
	Target	Ave	Max	Min		First	Last	High	Low

8.3.2.2 BLANKS 2010 -2013

Coarse blanks, including two from MEG and one created by Paramount using commercially available crushed rock, and analytical (pulp) blanks were also inserted into the drill sample stream. Based on the data compiled by RESPEC, Paramount inserted blanks at a rate of about one blank for every 30 samples. Any lab assay value greater than five times the detection limit was considered to be a failure that should be evaluated further.

A total of 231 coarse blanks were submitted with the drill samples and analyzed for gold and 230 for silver. No failures were returned. A total of 56 pulp blanks were submitted and analyzed for gold with no failures. RESPEC was also provided with a compilation of some ALS internal lab coarse blank results, comprised of eight blanks analyzed for gold and 10 for silver, and again no issues were found.

Figure 8-7 shows the gold values of the coarse blanks plotted with the preceding values. Notice that some of the higher blank gold values, while not failures, are often associated with high preceding drill sample values, which indicates an immaterial amount of cross-contamination from the prior sample into the drill sample.

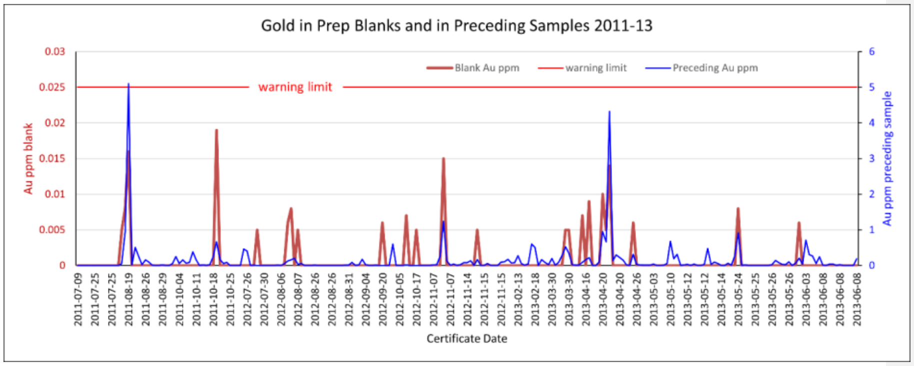

Figure 8-7 Gold Values of Paramount Coarse Blanks and Preceding Samples

8.3.2.3 PARAMOUNT DUPLICATES

Pulp Duplicates and Preparation Duplicates. Paramount's pulp and preparation duplicate data were in the process of final compilation and subsequent analysis as of the date of this report.

Field Duplicates. A total of 137 RC field duplicates were compiled from Paramount's 2011 to 2013 drill program. Figure 8-8 shows an RPD plot of the 121 of the field duplicate pairs; pairs in which both the original and duplicate analyses are less than the detection limit were excluded.

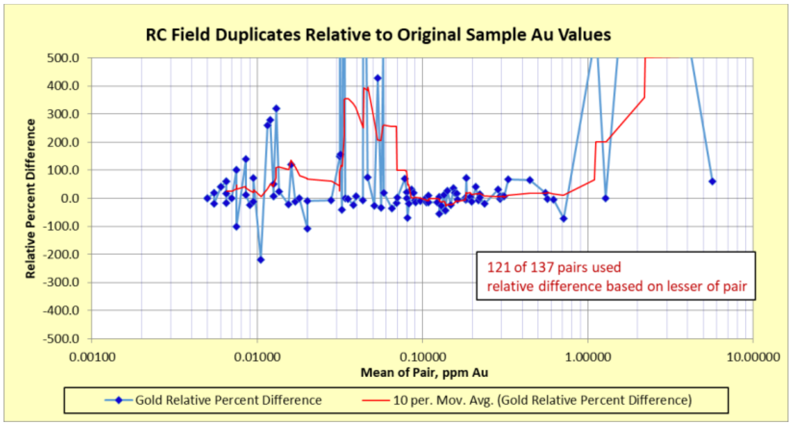

Figure 8-8: Paramount Gold RC Field Duplicates, Relative Differences 2010-2013

No bias at relevant grades (≥ 0.1 g Au/t) is evident. Five of the 51 pairs that have a mean-of-the-pairs ≥ 0.1 ppm exceed an AV of the RPD of 100%, and these five pairs are among the highest-grade pairs of this limited dataset, ranging from 1.1 to 2.2 ppm.

There are even fewer core field-duplicate pairs in which at least one of the duplicate and original analyses are greater than the detection limit (Figure 8-9). In this case, the available data show a consistent low bias, in which the duplicate analyses tend to be lower than the original drill sample assays. More data are needed to confirm this bias, however. Three of the 26 pairs with mean-of-the-pairs ≥ 0.1g Au/t have AVs of the RPDs in excess of 100%.

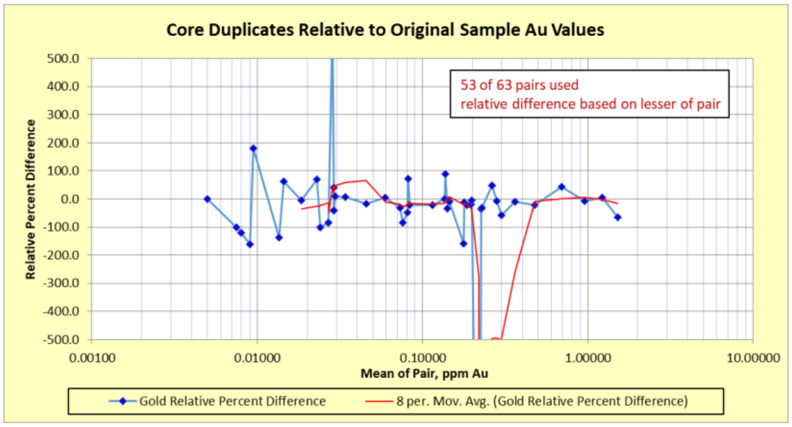

Figure 8-9: Paramount Gold Core Field Duplicates, Relative Differences 2010-2013

8.4 ADEQUACY OF SAMPLE PREPARATION, ANALYSES AND SECURITY

The sample preparation, analytical, and security procedures implemented by Paramount and historical operators were all within conventional industry norms. While the documentation of the QA/QC programs of the historical operators reviewed by RESPEC to date is not complete, Paramount and RESPEC continue to review historical information and compile relevant data. Even the compilation, verification, and evaluation of Paramount QA/QC information remains ongoing. Irrespective of the ongoing evaluation, based on the information RESPEC has reviewed to date, there is little evidence of what, if any, actions were taken by historical operators to address QAQC failures that may have been identified.

As of the date of this report, potential RC sample-splitting issues in the 2003-2007 X-Cal drilling have been identified and require further evaluation to ascertain whether the problem was restricted to certain periods of drilling and/or specific areas of the deposit. It is important to note that, to the extent there is an issue, the effect is that a relatively small portion of X-Cal's RC drill sample gold values may be understated.

The most significant issue identified is the high variability that is an inherent characteristic of the Sleeper gold-silver mineralization. As discussed, while this variability is expected due to the nature of the Sleeper mineralization, it must be addressed throughout the entire process of resource modeling.

It is the opinion of RESPEC that the sample preparation, analyses, and security of the Sleeper project operators resulted in data that are adequate as used in this report, most importantly to support the estimation of Inferred gold and silver resources.

9.0 DATA VERIFICATION

The current Sleeper drill hole database, which forms the basis for the Sleeper resource estimation, is comprised of information derived from 4,261 holes. A total of 3,994 of these holes were drilled in the general area of the Sleeper resources, including 132 Paramount holes and 3,862 historical holes. This database was then subjected to the data verification procedures discussed below and corrections were made as appropriate.

9.1 SITE VISIT

RESPEC visited the project site on four separate occasions: April 19 and November 18, 2021; and March 2 and May 11, 2022. During these visits, RESPEC inspected altered and mineralized drill core samples from several drill holes from the Sleeper deposit area and reviewing all project procedures related to logging, sampling, and data capture completed by Paramount. RESPEC inspected the conditions of sample storage at site and if historical pulps were in suitable condition for resampling. Several drill hole locations were visited while in the field and GPS coordinates were collected to compare against collar coordinates in the database. Part of the visit also included time at the Winnemucca office reviewing the status and condition of the historical drill logs, assay certificates, and other paper records. RESPEC reviewed the cross-sectional geological modeling generated by Paramount geologists and consultant Don Hudson that was eventually used as a base for resource modeling.

9.2 DRILLING DATABASE VERIFICATION

Data verification is the process of confirming that data have been generated with proper procedures, have been accurately transcribed from the original sources and are suitable to be used. Additional confirmation of the drill data's reliability is based on the evaluations of the Sleeper drill project QA/QC procedures and results, as described previously, and in general working with the data. No separate evaluations of QA/QC procedures and results were done on data from drilling outside the mineral resource areas.

Beginning in May 2022, RESPEC conducted verification of Paramount's spreadsheet database in two phases: Phase 1, run a series of logical tests against the current modeling database to test for data integrity issues, and correct or explain and document any issues; Phase 2, build a new database from drill collar coordinates, down-hole survey data, and certificates in GeoSequel.

All collar coordinate and down-hole survey data was received as composited digital files from Paramount. The certificate data was all obtained from downloaded certificate files found in a data repository for the project. None of the certificates were downloaded directly from the laboratory by RESPEC. This database was then compared against Paramount's database to look for data entry issues.

The initial phase (Phase 1) logical tests of the database included a series of queries to validate the modeling database (Sleeper Project Excel database). The following validation tests were conducted to identify:

- Collars: collars with missing depths, collars with missing coordinates, coordinates that might be swapped, drill holes without assay intervals, drill holes without collar survey information, drill holes with nearly duplicate coordinates, drill holes without assays, drill holes without geology, and drill holes with geotechnical information (core holes only).
- Down Hole Surveys: survey depths greater than total depth, survey points missing azimuth or dip values, surveys where azimuth readings were not between 0 and 360 degrees, surveys with flat dip angles (< ~ 45°); and down-hole survey points with excessive rate of change.
- Assay interval: "excessively" large or small sample intervals, "excessively" large or small geologic intervals, assay intervals that are greater than collar total depth, geologic intervals that are greater than total depth, gaps, and overlaps in sample intervals, gaps, and overlaps in geologic intervals.

When minor data integrity issues were found, they were evaluated and if warranted, corrected in the modeling database. Data issues were resolved using the data repository supplied by Paramount.

9.2.1 DRILL COLLAR LOCATIONS

Since the initial exploration during the early-1980s of the Sleeper Gold Property AMAX established a local grid coordinate system using a truncated state plane, NAD27, Western Nevada Zone system in feet: local X of 0 = State Plane X of 640,000; local Y of 0 = State Plane Y of 2,390,000 (. This local coordinate system remained in use for all data systems through to August of 2004. As of the end of August 2004, X-Cal converted all pertinent data, including the drill hole coordinates, to the Universal Transverse Mercator (UTM) NAD1927, Zone 11 coordinate projection system in meters: local Mine Grid X of 0 = UTM X of 410,125.39; local Mine Grid Y of 0 = UTM Y of 4,573,808.38. All holes from subsequent drilling programs were surveyed in UTM coordinates.

The Paramount drilling programs have been surveyed in UTM coordinates. Paramount has not resurveyed any historical drill hole collars because they were either mined out as part of operation or reclaimed as apart of mine closure. An on-going program of spot checking original digital files produced by the survey contractor compared to those in the existing database is currently in progress. Checking the total depths of historical holes against historical records is also in progress.

9.2.2 DOWN-HOLE SURVEYS

Down-hole survey data was received as composited digital files from Paramount. An on-going program of checking 10% of the drillholes original survey files produced by survey contractors compared to those in the existing database is currently in progress.

9.2.3 DRILLING ASSAY DATABASE

The second phase of the data validation was the most comprehensive, comparing the independently built Sleeper Project database to a database created from raw certificates acquired from Paramount in both pdf and csv form. Of the 4,330 certificates imported into the GeoSequel system, all were presumed to be the original download from ALS Minerals (Chemex Labs), American Assay, Inspectorate Labs, or ACME Labs. When the original certificate could not be found, the drill hole assay data was created as an artificial certificate from the cleaned-up Paramount data. Of the 4,330 total certificates imported, 674 were imported from the digital certificate as supplied by Paramount staff, and 3,656 were created from data as supplied.

An on-going program of spot checking these data is currently in progress. A digital audit was performed on all the 289,826 total data rows for the gold and silver columns. After accounting for the differences in the way the Paramount database handled below detection limit values, 541 differences for gold and 675 for silver existed. These were manually evaluated to determine the best values. For the gold differences, 409 were found to be where Paramount had not correctly prioritized the values – not prioritizing a metallic fire screen assay over an ICP assay, or using a duplicate, repeat, or re-run sample inconsistently. Minor rounding differences from converting from the original units accounted for 120 of the gold differences, and the rest were typographical errors or sourcing errors. For the silver differences, most of these (333) were conversions issues, 264 were prioritization issues, and 78 were typographical errors. All errors and inconsistencies were evaluated and corrected as needed.

Of the 4,261 drill holes in the GeoSequel database, 266 of holes were flagged as 'model not use' in the drill collar file, flagging drill holes located outside the block model area. Notations of contamination from historical logs were noted in the assay database by interval. Additional contamination was identified during modeling of gold and silver domains. Down-hole contamination can sometimes be detected by careful inspection of the RC drill results in the context of the geology (e.g., anomalous to significant assays returned from samples from post-mineral units), by comparison with adjacent core holes, and by examining down-hole grade patterns. Contamination identified during modeling was added to the historical contamination notes. This resulted in 14,389 assay intervals being flagged as not use in resource estimation. Particular attention was paid to gold, additional work is needed to identify contamination for silver.

9.2.4 GEOLOGIC DATA

Paramount geologists and consultant Don Hudson relogged and reinterpreted several historical drill holes in 2013. From the reinterpretation program a lithologic, oxidation, and structural 2D model was built using E-W oriented vertical sections, spaced every 50 meters in the center of the deposit, and spaced every 100 meters at the North and South end of the deposit. The 3D lithologic solids were based on polygon modeling in sections, and snapping to the drilling, and were used in the coding of the resource model.

Comparing the 3D lithologic and structural model to the historical drill logs proved to be difficult due to vague or missing rock descriptions. The quality of drill logs varies considerably; some drill holes are described well enough to determine lithologic boundaries whereas others could only be used to define a bedrock-alluvium contact.

When evaluating the oxidation model, it was quickly apparent that a typographical error had occurred at some point when data was transcribed electronically where the code for the oxide zone had been exchanged with the sulfide code. This inversion of the sulfide and oxide zones is fundamentally incorrect and easily disproved by historical mining records produced by AMAX. RESPEC strongly recommends that Paramount investigate this coding swap before proceeding with database changes.

9.3 ADEQUACY OF DATA

RESPEC experienced some limitations with respect to data verification for the Sleeper project. In consideration of the information summarized in Sections 5 through 9 and 11 of this report, RESPEC has been able to verify that recent data with digital certificates collected by Paramount and X-Cal are acceptable to use to support estimation of the mineral resources. The vast majority of historical data has very little original source certificates and documentation available in digital formats to verify against the database. This has resulted in a much more time-intensive verification process that is still in progress as of the effective date of the resource estimate. RESPEC believes that despite the verification process being partially complete, it did not preclude the ability to produce a mineral resource estimate, albeit at a lower classification than might otherwise be determined in a fully validated database.

10.0 MINERAL PROCESSING AND METALLURGICAL TESTING

This section has been prepared under the supervision of Mr. Jeffrey L. Woods, of Woods Process Services LLC. The information presented below was received from Paramount and sources as cited. Mr. Woods has reviewed this information and believes it to be materially accurate.

10.1 PARMOUNT METALLURGICAL TESTS

This section summarizes metallurgical test work performed by McClelland Laboratories, Inc. (MLI) of Sparks, Nevada on Sleeper drill hole samples. Specifically, this report is a summary of the following reports:

- Report #1: Phase 2 Metallurgical Evaluation – Waste Dump, Westwood and Facilities Composites ("bench" scale tests); MLI Job No. 3486-01; January 27, 2012
- Report #2: Heap Leach Amenability Study – Sleeper Waste Rock Composites (5) and Facilities Oxide Core Composites (2); MLI Job No. 3486-01; August 16, 2012
- Report #3: Metallurgical Tests and Analyses on 12 Sleeper Project Core Composites; MLI Job No. 3775; July 28, 2014
- Report #4: Biooxidation and Pressure Oxidation Testing – Sleeper Drill Core Composites; MLI Job No. 3775; May 26, 2015 (includes Gold Deportment Mineralogical Study on 3 Samples; SGS Project 14322-001; February 10, 2014)

This report presents a summary of the test results of the four reports listed above, and this report is not intended to present all of the details contained in the reports. The purpose is to bring the results of these reports into one compiled summary.

The summary of results presented herein is organized in two parts, Test Series 1 and Test Series 2. Test Series 1 includes the tests reported in Reports #1 and #2. Test Series 2 includes the tests reported in Reports #3 and #4.

10.1.1 TEST SERIES #1

Waste Dump Sonic Drill Samples

Test results show that waste dump material is generally amenable to agitated cyanidation treatment at P_{80} 19mm (3/4") crush size. Gold recoveries ranged from 49.0% to 89.7%, averaging 69.7% with 96 hours of cyanidation. Silver recoveries were lower and ranged from 18.2% to 52.1%. Average Ag recovery was 34.5%. NaCN consumptions were high for the south waste dump composites but relatively low for the west and north waste dump composites. Lime requirements were relatively high (>3kg/mt), especially for the north waste dump composites.

Flotation tests on waste dump material showed very high mass pulls to concentrate (43.3% and 49.5%). Gold recoveries were 67.1% and 69.2%. Silver recoveries were 67.2% and <61.7%.

Column percolation leach tests on waste dump composite samples were performed at P_{80} 19mm feed size. Gold recoveries were 63.6% and 75.9% for the south dump composites. Gold recoveries were somewhat higher (81.0% and 81.8%) for the west dump composites. Gold recovery for the north dump (HG) sample was 79.0%. Leaching was relatively fast, with gold extraction substantially complete in twenty (20) days. Cyanide (NaCN) and cement consumptions were moderate to high for the south dump and west dump samples. The cement requirement for the north dump sample was exceptionally high. No lime addition was used in these column leach tests.

Westwood and Facilities Core Drill Samples

Westwood core composites (WAS, argillic silicic and WSS, strong silicic) had low direct cyanidation metal recoveries at P_{80} 19mm and P_{80} 75µm feed sizes (5.9% to 36.5% gold recovery). Flotation recoveries were better, but further work would be required to optimize performance to achieve acceptable metallurgical results. Concentrate regrinding, and possibly ultrafine grinding may be viable options to improve metallurgical performance.

Bond comminution tests were performed on two (2) Westwood composites. Make-up of these composites was not clearly stated, but it is assumed these were sulfide composites. Bond ball mill work index (BWi) results were 18.55 and 20.53 kWH/st. These results classified this material as hard. Abrasion index (Ai) results were 0.1894 and 0.1391. These results showed the material had moderate abrasiveness.

Facilities core composites (both oxide and sulfide) were amenable to direct cyanidation (bottle roll tests) at P_{80} 19mm feed sizes. Sulfide composites were tested at P_{80} 75µm, and the reduced feed size improved metal recoveries noticeably. Oxide composites were not subjected to cyanidation tests at the P_{80} 75µm feed size.

Bond ball mill work index (BWi) results on Facilities sulfide composites were 7.53 and 8.73 kWH/st. These results classified this material as soft. Abrasion index (Ai) results were 0.0011 and 0.0060. These results showed the material had light abrasiveness.

Column percolation leach tests on Facilities oxide composite samples were performed at P_{80} 19mm feed size. Gold recoveries were 83.1% and 84.6%. Leaching was relatively fast, with gold extraction substantially complete in twenty (20) days. Cyanide (NaCN), cement and lime consumptions were moderate. Despite the relatively high gold recoveries obtained in the bottle roll leach tests, column leach tests were not performed on the Facilities sulfide composite samples.

10.1.2 TEST SERIES #2

Results show that Facilities mixed ore was amenable to bottle roll cyanidation at P_{80} 37.5mm (1-1/2") and P_{80} 19mm (3/4") crush sizes. Gold recoveries were 71.3% and 74.2%, respectively. Facilities sulfide ore was not amenable to bottle roll cyanidation at either of the crush sizes (~25% gold recovery), which is significantly different than the results obtained in Test Series 1. In Test Series 1, gold recoveries for Facilities sulfide composites were 92.8% and 80.4% for the P_{80} 19mm bottle roll tests.

Lower grade West Wood oxide ore was amenable to bottle roll cyanidation. Gold recovery at P_{80} 19mm was 76.4%. Gold recovery at P_{80} 75µm was 80.7%.

Higher grade West Wood oxide ore was marginally amenable to bottle roll cyanidation at P_{80} 19mm crush size. Gold recovery was 53.6%. Gold recovery increased to 82.8% for the ground P_{80} 75µm feed. It is important to note that the column leach test gold recovery for this composite, at P_{80} 19mm crush size, was significantly better (70.8% gold recovery).

Sleeper oxide ore was readily amenable to bottle roll cyanidation at P_{80} 19mm crush size. Gold recovery was 93.9%. No other feed sizes were tested on this composite because Sleeper oxide ore was nearly "mined out" during previous commercial heap leach operation.

The West Wood, Sleeper and South Sleeper sulfide composites were not amenable to bottle roll cyanidation at P_{80} 75µm grind size. Gold recoveries were ~29% for West Wood, ~40% for Sleeper and <23% for South Sleeper.

Wood sulfide ore was not amenable to bottle roll cyanidation at P_{80} 19mm crush size (12.9% gold recovery). Grinding the ore to P_{80} 75µm did not increase cyanidation recovery to acceptable levels (48.5% gold recovery).

For the above bottle roll tests, NaCN consumptions were low for mixed and oxide ore composites (<0.05 to 0.18 kg/mt ore) and generally high for sulfide ore composites (>0.5 kg/mt ore). Lime requirements (lime added) were generally high (>3 kg/mt ore) for all ore composites.

Facilities mixed ore was amenable to heap leach cyanidation at P_{80} 37.5mm and P_{80} 19mm crush sizes. Gold recoveries were 77.1% and 71.3%, respectively, suggesting the finer crush size had no benefit.

West Wood oxide ores were amenable to heap leach cyanidation treatment at P_{80} 19mm crush size. Gold recoveries were 70.8% (higher grade composite) and 82.1% (lower grade composite). These recoveries were achieved in 139 and 67 days of leaching and rinsing, respectively.

Facilities sulfide ore was not amenable to heap leach cyanidation. Column leach test gold recovery was 12.9% in 88 days of leaching and rinsing.

For the column leach tests above, NaCN consumptions were high. Typically, NaCN consumption in commercial heap leaching is substantially lower. Lime requirement (lime added) was moderate to high. Lime added before leaching was sufficient to maintain leach pH above 10.

Pursuant to the bottle roll and column leach tests performed above, preliminary stirred tank biooxidation and pressure oxidation (POX) tests were conducted on three refractory sulfide drill core composites from the Wood and West Wood areas of the project. The purpose of these tests was to determine if gold recovery could be improved by oxidative pretreatment of the ore. Biooxidation testing consisted of batch stirred tank biooxidation tests, at P_{80} 45µm grind size, followed by carbon-in-leach/cyanidation

(CIL) of the biooxidized residues. POX testing consisted of a single batch POX test, at P_{80} 80μm grind size, followed by CIL of the POX residue.

All three composites responded very well to batch stirred tank biooxidation treatment. Gold recoveries obtained by CIL were significantly improved (90.6% to 96.0%) after 21 to 28 days of biooxidation. CIL reagent consumptions for the biooxidized residues were moderate.

Biooxidation rates were rapid for the West Wood composites. Biooxidation rate was slower for the Wood composite, but not unusually slow for batch stirred tank biooxidation tests. Relatively high levels of sulfide oxidation (>90%) were achieved for all three composites.

A single batch POX test was conducted by Hazen Research, under the direction of MLI, on each of the three composites. All three composites responded well to POX processing. Gold recoveries ranged from 85.9% to 92.5%. Reagent consumptions were higher than for batch biooxidation tests, but not considered unusually high for such preliminary testing. Sulfide sulfur oxidation obtained by POX pretreatment ranged from 77% to 82%. Optimization of grind size and POX process conditions could result in higher levels of sulfide oxidation and gold recovery.

Although the results from preliminary stirred tank biooxidation and POX tests showed good technical potential for processing the Sleeper refractory ore types tested, the grade range of the composites tested (1.1 to 3.1 g Au/mt ore) did not appear sufficiently high to offset the high capital and operating costs associated with these process methods. Accordingly, evaluation of heap biooxidation processing of these ore types was performed on three (3) sulfide composites. The composites were from the Westwood, Wood and Facilities areas of the project.

Simulated heap biooxidation pretreatment was effective in significantly improving gold recovery by cyanidation. Baseline gold recoveries obtained from the three composites, at both P_{80} 12.5mm (1/2") and P_{80} 6.3mm (1/4") feed sizes, ranged from 11.9% to 20.6%, in 67 to 109 days of leaching and rinsing. Gold recoveries obtained from cyanidation of the biooxidized residues, at the 12.5mm feed size, ranged from 65.4% to 71.9%, in 85 to 92 days of leaching and rinsing. Gold recoveries from the P_{80} 6.3mm biooxidized residues ranged from 68.7% to 81.0%, in 87 to 93 days of leaching and rinsing.

Cyanidation gold recovery rates were relatively rapid. Biooxidation was terminated for these tests after 235 days, and sulfide sulfur analysis of the biooxidized residues indicated sulfide oxidation ranged from 22.0% to 54.9%. Further analysis of the data from the sacrificial column tests run in this test program indicated that an adequate biooxidation cycle time could be significantly less than 235 days. Further testing would be required to confirm that observation. At some point, a large scale biooxidation test would need to be performed to properly assess this process option.

Cyanide consumptions for the biooxidized residues were high (2.50 to 3.55 kg NaCN/mt ore). Lime required to maintain pH during cyanidation of the biooxidized residues was very high (12.7 to 37.7 kg/mt ore). It is important to note that this lime requirement does not include the lime or limestone that would be required for neutralizing acid generated during biooxidation pretreatment in a commercial circuit. The global base requirement is probably best estimated based on the sulfide sulfur grade, mineralogy of the feed, and the levels of oxidation required.

Solution percolation problems were observed during biooxidation pretreatment of all three composites, at the P_{80} 6.3mm feed size. Those problems ranged from minor to relatively severe. In general, no significant solution percolation problems were encountered during biooxidation of the P_{80} 12.5mm feeds. The notable exception was the Facilities composite, which displayed moderate solution percolation problems in the P_{80} 12.5mm test. All cyanidation column charges (baseline and biooxidized residues) were agglomerated, using the lime required for pH control, before leaching. No solution percolation problems were encountered during cyanide leaching. No geotechnical (load/permeability) testing was conducted on the biooxidized residues or cyanide leached agglomerates, to evaluate permeability expected during commercial heap biooxidation and leaching. It is expected that load/permeability testing will be required, and that testing may lead to additional optimization of crush size and agglomerating conditions.

10.2 DISCUSSION

10.2.1 TEST SERIES #1

Report #1 – Waste Dump Test Program

Report #1 presents results of metallurgical tests performed on composite samples prepared from sonic drill hole intervals from three waste dumps. The waste dumps were designated as North, South and West Waste Dumps. There were three sonic drill holes from each of the three waste dumps resulting in nine total holes used in the waste dump test program. Table 10-1 below summarizes the composite make-up information.

Table 10-1. Waste Dump Composite Make-Up Information

AREA	COMPOSITE ID	HOLE	FROM	TO	COMMENTS
South Waste Dump	WDS-11-1	WDS-11-1	0	39.3	from/to in meters, sonic drill hole
South Waste Dump	WDS-11-2	WDS-11-2	0	37.8	from/to in meters, sonic drill hole
South Waste Dump	WDS-11-3	WDS-11-3	0	25	from/to in meters, sonic drill hole
West Waste Dump	WDW-11-4	WDW-11-4	0	21	from/to in meters, sonic drill hole
West Waste Dump	WDW-11-5	WDW-11-5	0	16	from/to in meters, sonic drill hole
West Waste Dump	WDW-11-6	WDW-11-6	0	18.3	from/to in meters, sonic drill hole
North Waste Dump	WDN-11-9 HG	WDN-11-9	0	20	from/to in meters, sonic drill hole
North Waste Dump	WDN-11-7,8+9	WDN-11-7	0	43	from/to in meters, sonic drill holes
		WDN-11-8	0	27.4	
		WDN-11-9	0	33.5	

A review of the sonic drill hole locations shows the holes listed above were significantly spaced apart (for example, 300 to 400 meters in the north dump). Accordingly, it is questionable as to how well the small number of samples represent the metallurgical performance of the entirety of waste dump material. There were a significant number of sonic drill holes put into the waste dumps, which were not tested. If material is still available, it may be possible to perform variability bottle roll tests and correlate those results to the test results reported herein.

The tests performed on waste dump composite samples were as follows:

- Bottle roll cyanidation tests (BRTs) at P_{80} 19mm (3/4") feed size [all eight composites]
- Bulk sulfide flotation tests on two North Waste Dump composites (WDN-11-9 HG and WDN-11-7,8+9)

Table 10-2 below summarizes the results of the P_{80} 19mm BRTs.

Table 10-2. Summary Metallurgical Results, Agitated Cyanidation Tests, Sleeper Waste Dump Composites, P_{80} 19mm Feeds

Hole Composite I.D.	Interval, Meters	Au Rec., %	gAu/mt ore			Ag Rec., %	gAg/mt ore			Reagent Consumption, kg/mt ore	
			Extracted	Tail	Calc. Head		Extracted	Tail	Calc. Head	NaCN Cons.	Lime (Added)
WDS-11-1	0-39	73.4	0.1388	0.0503	0.1891	52.1	1.087	1.000	2.087	0.79	9.6
WDS-11-2	0-37.8	55.4	0.1599	0.1253	0.2812	35.0	1.078	2.000	3.078	1.42	13.0
WDS-11-3	0-25	49.0	0.1183	0.1233	0.2416	36.8	1.165	2.000	3.165	0.91	7.4
WDW-11-4	0-21	66.5	0.1223	0.0617	0.184	18.2	0.296	1.333	1.629	0.23	2.9
WDW-11-5	0-16	89.7	0.24	0.0277	0.2677	35.2	0.544	1.000	1.544	0.08	3.3
WDW-11-6	0-18.3	85.4	0.22	0.0377	0.2577	30.9	0.447	1.000	1.447	0.08	3.4
WDN-11-HG	0-20	78.8	0.3833	0.103	0.4863	38.6	1.680	2.667	4.397	0.23	42.9
WDN-11 Master	N/A[1)]	59.2	0.2554	0.1757	0.4311	29.0	1.634	4.000	5.634	0.38	29.5

1) Master composite prepared on a weighted basis from all drill intervals from sonic drill holes WDN-11-7, 8 and 9.

Gold recovery ranged from 49.0% to 89.7%, with an average of 69.7%. Silver recovery ranged from 18.2% to 52.1%, with an average of 34.5%. The waste dump material is generally amenable to bottle roll cyanidation at 19mm feed size. Cyanide consumptions were high for the WDS composites, but relatively low for the WDW and WDN composites. Lime consumptions were high for the WDS composites, typical for the WDW composites and exceptionally high for the WDN composites.

Table 10-3 below summarizes the results of the bulk sulfide flotation tests (75µm grind size).

Table 10-3. Summary Metallurgical Results, Bulk Sulfide Flotation Tests (for Ro. Concs.), North Waste Dump Composites, P_{80} 75µm Feeds

Comp. I.D.	Product	Weight, percent	Ro. Conc. Assays, g/mt		Recovery, percent	
			Au	Ag	Au	Ag
WDN-11-9 HG	Ro. Conc.	43.31	0.826	8.03	67.1	67.2
WDN-11 Master	Ro. Conc.	49.48	0.439	<4.39	69.2	<61.7

Flotation performance was not good. The mass pulls to concentrate were very high (+40%), and the metal recoveries a little under 70%.

Report #1 – Core Drill Hole Test Program

In addition to the tests on waste dump samples, Report #1 presents results of metallurgical tests performed on composite samples prepared from core drill hole intervals from the West Wood and Facilities Areas of the project. Eight (8) core drill holes were used in the core test program. Table 10-4 below summarizes the composite make-up information.

Table 10-4. West Wood and Facilities Composite Make-Up Information

AREA	COMPOSITE ID	HOLE	FROM	TO	COMMENTS
West Wood	WAS1	PGC-10-004	633	673	from/to in feet, core drill hole
West Wood	WAS2	PGC-10-002	339.2	364	from/to in feet, core drill hole
West Wood	WAS3	PGC-10-003	864.5	893	from/to in feet, core drill hole
West Wood	WAS4	PGC-10-001	483	513	from/to in feet, core drill hole
West Wood	WSS1	PGC-10-003	710.5	767.5	from/to in feet, core drill hole
West Wood	WSS2	PGC-10-001	615.5	743	from/to in feet, core drill hole
West Wood	WSS3	PGC-10-001	773	796	from/to in feet, core drill hole
West Wood	WSS4	PGC-10-002	646	659	from/to in feet, core drill hole
Facilities	FOX-001	PGC-11-007 PGC-11-009	0 68.9	149.9 167.3	from/to in feet, core drill hole
Facilities	FOX-002	CFAC-01-04 PGC-11-010	85 104.99	150 249.34	from/to in feet, core drill hole
Facilities	FSUF-001	PGC-11-007	115.18	194.88	from/to in feet, core drill hole
Facilities	FSUF-002	PGC-11-007 PGC-11-009	194.88 200.1	214.89 232.9	from/to in feet, core drill hole

For comments regarding the location of these, and other core drill holes used for metallurgical testing, please refer to the discussion following Table 10-8.

The tests performed on core composite samples were as follows:

- Bottle roll cyanidation tests (BRTs) at P_{80} 19mm (3/4") feed size [all twelve (12) composites]
- Bottle roll cyanidation tests (BRTs) at P_{80} 75µm feed size [ten (10) composites, Facilities oxide composites tested at P_{80} 19mm only]
- Bulk sulfide flotation tests, P_{80} 75µm feed size [all twelve (12) composites]
- Cyanidation tests (BRTs) on select bulk rougher flotation tailing samples
- Bond ball mill work index (BWi) and abrasion index (Ai) determinations on Westwood and Facilities composites

Table 10-5 below summarizes the results of the P_{80} 19mm BRTs.

Table 10-5. Summary Metallurgical Results, Agitated Cyanidation Tests, Westwood and Facilities Core Composites, P_{80} 19mm Feeds and P_{80} 75µm Feeds

Hole Composite I.D.	Interval, Meters	Au Rec., %	gAu/mt ore			Ag Rec., %	gAg/mt ore			Reagent Consumption, kg/mt ore

The results show WAS (Westwood, argillic silicic) and WSS (Westwood, strong silicic) composites were not amenable to cyanidation at P_{80} 19mm. Reducing feed size to P_{80} 75µm did not improve metal recoveries to acceptable levels. Cyanide consumptions were low to moderate, and lime consumptions were generally high.

Facilities oxide composites were amenable to cyanidation at the P_{80} 19mm feed size. Gold recoveries were 80.7% and 81.1%. However, silver recoveries were low (<20%). Cyanide consumption was low and lime consumption was moderately high.

Facilities sulfide composites were amenable to cyanidation at the P_{80} 19mm feed size; gold recoveries were 92.8% and 80.4%. This is noteworthy. The high gold recoveries were not expected for sulfide material. Reducing particle size increased gold recoveries noticeably to 93.2% and 84.6%, respectively. Silver recoveries at the P_{80} 19mm feed size were 27.5% and 43.5%. Reducing particle size increased silvery recovery significantly to 33.3% and 55.0%. Cyanide consumption was low to moderate, and lime consumption was high.

Table 10-6 below summarizes the results of the bulk sulfide flotation tests (P_{80} 75µm grind size).

Table 10-6. Summary Metallurgical Results, Bulk Sulfide Flotation Tests (for Ro. Concs.), Westwood and Facilities Core Composites, P_{80} 75µm Feeds

Comp. I.D.	Product	Weight, percent	Ro. Conc. Assays, g/mt		Recovery, percent	
			Au	Ag	Au	Ag
WAS1	Ro. Conc.	23.9	2.322	60.52	79.7	76.0
WAS2	Ro. Conc.	27.0	3.487	4.32	57.7	26.9
WAS3	Ro. Conc.	25.2	3.139	13.76	72.1	69.8
WAS4	Ro. Conc.	18.7	1.591	5.25	73.5	>54.7
WSS1	Ro. Conc.	24.2	2.710	3.97	65.0	55.9
WSS2	Ro. Conc.	23.9	2.394	7.43	80.5	70.0
WSS3	Ro. Conc.	25.4	2.186	9.59	70.0	52.2

FSUF-001	Ro. Conc.	34.2	2.023	<4.29	70.7	<48.8
FSUF-002	Ro. Conc.	17.0	4.560	3.78	91.2	43.6
FOX-001	Ro. Conc.	24.3	1.748	4.38	62.7	29.7
FOX-002	Ro. Conc.	23.3	1.927	2.70	60.8	<21.5

The report noted that cleaner flotation recoveries were generally poor. Therefore, only rougher flotation data was presented. It should be noted that the flotation tests performed were scoping in nature and no attempt was made to optimize parameters. It may be possible to improve flotation performance by optimizing parameters.

Mass pulls to concentrate were high for the WAS and WSS composites. Excluding WSS4, which had an exceptionally high mass pull (51.9%), mass pulls to concentrate generally ranged from 18% to 27%. Except for WAS2, which had a gold recovery of 57.7%, WAS gold recoveries ranged from 72.1% to 79.7%. Silver recoveries for WAS composites ranged from 26.9% (WAS2) to 76.0% (WAS1).

Gold recoveries for WSS composites ranged from 65.0% to 84.9%, and silver recoveries ranged from 52.2% to 90.2%.

Mass pulls to concentrate for Facilities sulfide composites were 34.2% and 17.0%. Gold recoveries were 70.7% and 91.2%. Silver recoveries were <48.8% and 43.6%. It is interesting to note that the lower mass pull corresponded with the higher gold recovery.

Mass pulls to concentrate for the Facilities oxide composites were 23.3% and 24.3%. Gold recoveries were 62.7% and 60.8%. Silver recoveries were 29.7% and <21.5%.

Cyanidation tests were performed on select Westwood and Facilities rougher flotation tailing samples (WAS2, WAS3, WSS1, WSS3, WSS4 and FSUF-001). For Westwood composites, gold recoveries were low and ranged from 22.9% (WAS3) to 59.4% (WAS2), averaging 37.8%. The Facilities rougher tail gold recovery was relatively high (86.5%).

Bond ball mill work index (BWi) and abrasion index (Ai) tests were performed on samples identified in the Phillips Enterprises, LLC (PE) report (dated January 16, 2012) as W-01, W-02, FSU-001 and FSU-002. The PE report identifies these as waste dump sonic samples, which is incorrect. Report #1 states these samples are core samples from the Westwood and Facilities areas of the project, but Report #1 does not clearly identify the make-up of the composites sent to PE. It is assumed the four (4) samples are sulfide composites. The BWi (75µm close size) and Ai results were as follows:

- W-01: BWi = 20.53 kWH/st (22.63 kWH/mt), Ai = 0.1894
- W-02: BWi = 18.55 kWH/st (20.45 kWH/mt), Ai = 0.1391
- FSU-001: BWi = 7.53 kWH/st (8.31 kWH/mt), Ai = 0.0011
- FSU-002: BWi = 8.73 kWH/st (9.63 kWH/mt), Ai = 0.0060

The Bond ball mill work indices for Westwood composites indicated hard milling material. The abrasion indices indicated moderate abrasiveness.

The Bond ball mill work indices for Facilities composites indicated soft milling material. The abrasion indices indicated light abrasiveness.

Report #2 – Column Leach Tests

Report #2 presents column percolation cyanidation test results that were completed after Report #1 was issued. The column leach tests were performed on five (5) Sleeper Waste Dump composites and two (2) Sleeper core composites. Specifically, the composites tested were:

- WDS-11-1
- WDS-11-2+3
- WDW-11-4
- WDW-11-5+6
- WDN-11-9 HG
- FOX-001
- FOX-002

The composite make-up information for these composites is summarized earlier in this report.

Note: Composite WDW-11-2+3 was created on a weighted basis from WDW-11-2 and WDW-11-3, and composite WDW-11-5+6 was created on a weighted basis from WDW-11-5 and WDW-11-6.

Table 10-7 below shows the results of the column leach tests (P_{80} 19mm crush size).

Table 10-7. Summary Column Percolation Leach Test Results,
Sleeper Waste Dump and Facilities Oxide Core Composites, P_{80} 19mm Feeds

Composite I.D.	gAu/mt ore			Au Recovery, %	Reagent Requirements, kg/mt ore	
	Extracted	Tail	Calc. Head		NaCN Cons.	Cement/Lime
WDS-11-1	0.173	0.055	0.228	75.9	1.44	10.0
WDS-11-2+3	0.164	0.094	0.258	63.6	1.74	10.0
WDW-11-4	0.108	0.024	0.132	81.8	0.94	3.5
WDW-11-5+6	0.204	0.048	0.252	81.0	0.83	3.5
WDN-11-9 HG	0.392	0.104	0.496	79.0	1.09	40.0
FOX-001	0.587	0.107	0.694	84.6	0.84	5.0/4.5
FOX-002	0.719	0.146	0.865	83.1	0.88	4.0/3.7

The results show the Waste Dump and Facilities oxide composites were amenable to agglomeration-heap leach cyanidation processing at a P_{80} 19mm crush size. Gold recoveries were somewhat lower for the South Waste Dump (WDS) composites. Gold recovery was relatively fast; extraction was substantially complete in 20 days of leaching. NaCN consumptions were high, but commercial consumption should be lower. For waste dump composites, cement requirements for agglomeration and pH control during leaching were moderate (WDW) to high (WDS). Cement requirement was extremely high for WDN-11-9 HG, mostly for pH control. For Facilities composites, lime was used in addition to cement, and consumptions of both were moderate.

It was stated in Report #2 that, "Because of the low-grade nature of the Waste Dump composites, even though Au recoveries were relatively high, heap leach processing may not be economically feasible unless waste dumps have to be moved to facilitate new planned production activity." This is a fair statement, but given higher current metal prices, the value of waste dump material may have increased enough to be viable, especially if used for heap leach pad overliner material.

10.2.2 TEST SERIES #2

Report #3

Whole core from eight (8) drill holes was received for interval preparation and assay. Subsequent to assay results, twelve (12) composite samples were prepared from intervals from seven (7) of the holes (PGC-13-034 was not used). Table 10-8 below shows the composite make-up information.

Table 10-8. Sleeper Project Composite Make-Up Information

AREA	COMPOSITE ID	HOLE	FROM	TO	COMMENTS
Facilities	FMX-13-1	PGC-12-028	162	234	from/to in feet, core drill hole
		PGC-13-031	20.2	200	
Facilities	FSU-13-1	PGC-12-028	435	745	from/to in feet, core drill hole
Sleeper	SOX-13-1	PGC-13-032	76.5	172.5	from/to in feet, core drill hole
Sleeper	SSU-13-1	PGC-12-029	1450	1575	from/to in feet, core drill hole
Sleeper	SSU-13-2	PGC-12-029	1180	1355	from/to in feet, core drill hole
West Wood	WWO-13-1	PGC-12-030	200	265	from/to in feet, core drill hole
West Wood	WWO-13-2	PGC-12-033	290	420	from/to in feet, core drill hole
West Wood	WWS-13-1	PGC-12-033	815	1060	from/to in feet, core drill hole
West Wood	WWS-13-2	PGC-12-033	625	681.5	from/to in feet, core drill hole
Wood	WOS-13-1	PGC-12-027	640	690	from/to in feet, core drill hole
South Sleeper	SSS-13-1	PGC-12-024	480	535	from/to in feet, core drill hole
		PGC-12-025	755	805	
		PGC-12-035	585	635	
South Sleeper	SSS-13-2	PGC-12-018	920	935	from/to in feet, core drill hole
		PGC-12-020	1050	1125	
		PGC-12-038	1130	1155	

A review of the core drill hole locations shows the holes listed above, and those listed in Table 4, provide reasonable coverage of the resource areas located beyond the historic Sleeper pit boundary (i.e. horizontally beyond). In general, the resource areas that lie beneath the historic Sleeper pit are not represented by the metallurgical testing reported herein. It is understood that obtaining core drill samples from the areas beneath the pit lake is not feasible and that historic mill metallurgical performance will have to be used for a PEA level report.

Table 10-9 below outlines the scope of work in this test program.

Table 10-9. Metallurgical Scope of Work Summary, Sleeper Project Core Composites

1) Average of all head grade determinations.

The results show Facilities mixed ore (FMX-13-1) was amenable to cyanidation at the two crush sizes tested [P_{80} 37.5mm (1-1/2") and P_{80} 19mm (3/4")]. Gold recovery was improved slightly at the smaller crush size.

In this series of tests, Facilities sulfide ore (FSU-13-1) was not amenable to cyanidation at the two crush sizes evaluated, which differed from the previous series of tests. In the previous series of tests, Facilities sulfide composites had relatively high gold recoveries (92.8% and 80.4%) at the P_{80} 19mm feed size. However, head grades were significantly higher in Series 1 (1.34 and 1.23 gAu/mt), versus 0.27 and 0.28 gAu/mt in this series, and higher recovery associated with higher head grade is not surprising. The comparison of results suggests there may be an opportunity to heap leach higher grade Facilities sulfide material if milling Facilities sulfide material is not economic.

Sleeper oxide ore (SOX-13-1) was readily amenable to cyanidation at the P_{80} 19mm crush size. No other tests were conducted on this composite as Sleeper oxide ore was nearly "mined out" during previous commercial heap leach operation.

Wood sulfide ore (WOS-13-1) was not amenable to cyanidation at the P_{80} 19mm crush size. Grinding the ore to P_{80} 75µm improved gold recovery significantly, but recovery remained below a viable level.

The lower grade West Wood oxide ore (WWO-13-1) was amenable to cyanidation and grinding to P_{80} 75µm improved gold recovery from 76.4% to 80.7%. The higher grade West Wood oxide ore (WWO-13-2) was marginally amenable to cyanidation at the P_{80} 19mm crush size (53.6% gold recovery). At P_{80} 75µm, gold recovery increased significantly to 82.8%. It is worthwhile to note the column percolation leach test recovery for the WWO-13-2 (P_{80} 19mm crushed feed size, discussed below) was higher (70.8%) than this P_{80} 19mm bottle roll leach test.

The Wood, West Wood, Sleeper and South Sleeper sulfide composites were not amenable to cyanidation at the P_{80} 75µm grind size.

NaCN consumptions were low for mixed and oxide ore composites (<0.05 to 0.18 kg/mt ore) but were generally high for sulfide ore composites (>0.5 kg/mt ore). Lime requirements (lime added) were generally high (>3 kg/mt ore) for all ore composites.

Table 10-11 below shows the results of the column leach tests (CT) performed on select samples. The bottle roll leach test (BT) results are included for comparison.

Table 10-11. Summary Metallurgical Results, Column Leach Tests, Sleeper Project Core Composites, P_{80} 37.5 and P_{80} 19mm Feeds (BT Results Included for Comparison)

Composite	Test Type	Feed Size, P_{80}	Au Rec., %	gAu/mt ore				Ag Ext'd, g/mt ore	Reagent Requirements, kg/mt ore		Final Leach pH

1) Average of all head grade determinations.

The Facilities mixed composite (FMX-13-1) was amenable to heap leach cyanidation treatment at the feed sizes tested. Gold recoveries were 77.1% [P_{80} 37.5mm (1-1/2")] and 71.3% [P_{80} 19mm (3/4")].

The West Wood oxide composites (WWO-13-1 and WWO-13-2) were amenable to heap leach cyanidation treatment at the feed size tested (P_{80} 19mm). Gold recoveries were 82.1% and 70.8%.

Gold extraction from the Facilities and West Wood oxide composite samples was achieved in 67 to 139 days of leaching and rinsing.

Facilities sulfide ore was not amenable to heap leach cyanidation, and gold recovery was only 12.9% in 88 days of leaching and rinsing.

NaCN consumptions were high, but consumption should be substantially lower during commercial heap leaching. Lime requirements (lime added) were moderate to high. Lime added before leaching was sufficient to maintain leach pH at above pH 10.

Report #4

Report #4 presents stirred tank biooxidation amenability, pressure oxidation and bioxidation column test results performed on three (3) sulfide core composite samples created for the previous test program (i.e. Report #3 phase of tests). Namely, the composites tested were: WWS-13-1, WWS-13-2 and WOS-13-1. Composite make-up information is outlined above in the previous section of this report.

Table 10-12 below shows the results of the stirred tank biooxidation amenability tests (P_{80} 45μm grind size).

Table 10-12. Summary Metallurgical Results, Cyanidation (CIL) Tests, Sleeper Drill Core Composites, 80%-45µm Feed Size

1) Adjusted for weight lost during biooxidation.
Note: BR denotes biooxidized residue.

All three (3) composites responded very well to batch stirred tank biooxidation treatment. Gold recovery obtained by CIL bottle roll testing of the biooxidation residues were >90%. Without oxidative pretreatment, gold recovery ranged from ~30% to ~50%. Biooxidation times ranged from 21 to 28 days. Reagent consumptions for the biooxidized residues were moderate.

Biooxidation rates were rapid for the WWS composites. Biooxidation rate was slower for the WOS composite, but not unusually slow for batch stirred tank biooxidation tests. Relatively high levels of sulfide oxidation (>90%) were achieved for all three composites.

A single batch POX test (P_{80} 80µm) was conducted by Hazen Research, under the direction of MLI, on each of the three composites. Results showed that all three composites responded well to POX processing. Gold recoveries obtained from the WWS-13-1, WWS-13-2 and WOS-13-1 composites, by CIL of the POX residues, were 92.5%, 90.0% and 85.9%, respectively. Reagent consumptions were higher than for batch biooxidation tests, but not considered unusually high for such preliminary testing. Sulfide sulfur oxidation obtained by POX pretreatment ranged from 77% to 82%. Higher levels of sulfide oxidation and gold recovery may be achievable through optimization of grind size and/or POX processing conditions.

Overall, preliminary test results showed good technical potential for processing the Sleeper refractory materials tested, either by biooxidation or POX pretreatment, followed by cyanidation. It was questionable, however, whether the grade range of the composites tested (1.1 to 3.1 g Au/mt ore) was sufficiently high to offset the high capital and operating cost associated with these process options. Considering the results, and the grade of the material tested, evaluation of heap biooxidation processing of these ore types was tested.

Due to constraints in sample availability, three different composites were selected for the heap biooxidation testing program. The composites tested were WWS-13-MC (master composite), WOS-MC (master composite) and FSU-13-1. The WWS-13-MC composite was created from available rejects from previously prepared composites WWS-13-1 and WWS-13-2. The WOS-MC composite was created from available rejects from WOS-13-1 and drill core intervals from lower in core drill hole PGC-12-033 that were not previously used.

Table 13 below shows the results from the heap biooxidation tests [P_{80} 12.5mm (1/2”) and P_{80} 6.3mm (1/4”) feed sizes].

Table 10-13. Summary Metallurgical Results, Continuous Column Leach Tests, Sleeper Drill Core Composites

Composite	Feed Size, P_{80}	Test Type	Estimated Sulfide Oxidation, %	Leach/Rinse Time, days	Au Rec., %	gAu/mt ore			Ag Rec., %	gAg/mt ore			Reagent Req., kg/mt ore

Note: BL denotes baseline. BR denotes cyanidation of a column biooxidized residue.

The baseline (BL) column leach tests were performed on untreated composite materials. The BR tests refer to bottle roll cyanidation of the biooxidation column residues. Column leach tests were not performed on the biooxidation column residues.

It is worthwhile to note that sacrificial biooxidation columns were run concurrently with the continuous columns (reported above in Table 13) to determine the biooxidation time required. Based on the sacrificial column results, the continuous biooxidation column tests were ended after 235 days of pretreatment.

Gold recoveries for the BL tests ranged from 11.9% to 20.6%. Gold recoveries for the BR tests ranged from 65.4% to 81.0%. These results indicated that gold recovery was significantly improved by simulated heap biooxidation followed by column leach cyanidation of the biooxidation column residues. Comparatively, the P_{80} 6.3mm feed size tests produced higher gold recoveries than the P_{80} 12.5mm feed size tests, in some cases significantly.

Cyanidation gold recovery rates were relatively rapid. Because the continuous biooxidation columns were operated without interruption during biooxidation, biooxidation rate data was not available. Sulfide sulfur oxidation ranged from 22.0% to 54.9%. Further analysis of the data from the sacrificial column tests indicated that a biooxidation cycle of significantly less time than 235 days may have been sufficient for obtaining the reported gold recoveries by cyanidation. The data suggests that decreased biooxidation time may be possible as well. Further testing would be required to confirm these observations, and at some point, large scale testing of heap biooxidation would be required to properly assess this process option.

Cyanide consumptions for the baseline column leach tests were high (1.55 to 2.83 kgNaCN/mt ore). Cyanide consumptions for the biooxidized residues were higher (2.50 to 3.55 kgNaCN/mt ore). Lime requirements for the baseline tests ranged from 3.4 to 6.6 kg/mt ore. Lime required to maintain pH during cyanidation of the biooxidized residues were substantially higher (12.7 to 37.7 kg/mt ore). It is important to note that these lime requirements do not include the quantities of lime or limestone that will be required for neutralizing acid generated during biooxidation pretreatment in a commercial circuit. The global base requirement is probably best estimated based on the sulfide sulfur grade and mineralogy of the feed, and the levels of oxidation required.

Solution percolation problems were observed during biooxidation pretreatment of all three composites, at the P_{80} 6.3mm feed size. Those problems ranged from minor to relatively severe. In general, no significant solution percolation problems were encountered during biooxidation of the P_{80} 12.5mm feeds. The notable exception was the FSU-13-1 composite, which displayed moderate solution percolation problems in the P_{80} 12.5mm continuous column test.

All baseline cyanidation test column charges were agglomerated, using the lime required for pH control, before leaching, and no solution percolation problems were encountered during cyanide leaching. No geotechnical (load/permeability) testing was conducted on the biooxidized residues or cyanide leached agglomerates to evaluate permeability expected during commercial heap biooxidation and leaching. It is expected that load/permeability testing will be required, and that testing may lead to additional optimization of crush size and agglomerating conditions.

Report #3/#4 – SGS Mineralogy Report

As part of the Series 2 phase of tests, samples of West Wood and Wood sulfide composites were sent to SGS for mineralogy and gold deportment analyses. Specifically, the composites analyzed were WWS-13-1, WWS-13-2 and WOS-13-1. The SGS report is included in the Report #4 appendix.

Rapid mineral scan results showed composites contained the following:

- 27% to 39% quartz
- 4.8% to 8.6% kaolinite, plus 26% to 32% other clays
- 13% to 21% K-spar
- 4.2% to 7.2% pyrite
- Minor amounts of arsenopyrite and stibnite

Gold mineralogy/deportment showed the following:

- Gold particles typically contained a significant amount of silver, and there was a significant amount of electrum (Ag:Au > 25%) present.
- Pyrite contained trace amounts of arsenopyrite, and arsenopyrite contained a trace amount of stibnite – both observations suggest potential for sub-microscopic gold.
- Gold grains in the West Wood composites were predominantly <10µm (>71% and >89%). Approximately 24% were between 10µm and 30µm. <5% were >30µm.
- Gold grains in the Wood composite were predominantly <5µm (>75%). Approximately 25% were between 5µm and 10µm. There were no grains observed >10µm.

- For West Wood composites, 30 grains were observed. 10 grains were liberated, 2 grains were exposed, and 18 grains were locked. The majority of the locked and exposed gold grains were associated with pyrite/quartz complexes or pyrite/silicate complexes. Exposed grains associated with pyrite ranged from only a few grains (WWS-13-1) to ~23% (WWS-13-2). A few grains observed in WWS-13-1 were associated with miargyrite ($AgSbS_2$).
- For the Wood composite, 20 grains were observed. 8 grains were liberated, 3 grains were exposed, and 9 grains were locked. Almost all of the locked and exposed gold grains were associated with quartz complexes. Only a few grains were associated with pyrite.

10.3 CONCLUSION AND RECOMMENDATIONS

10.3.1 TEST SERIES #1

Conclusions, observations and recommendations for this series of tests are summarized as follows:

- Waste Dump materials are generally amenable to cyanidation processing at P_{80} 19mm crush size. Reagent requirements are generally moderate to high (except for WDW dump composites).
- Facilities Sulfide and Oxide core composites were amenable to cyanidation treatment at P_{80} 19mm crush size. NaCN consumptions were generally low, but lime requirements were generally high.
- In contrast to the above, Facilities sulfide gold recoveries obtained in Test Series 2 were low. An investigation into the causes of this variance should be made. Was it simply an ore classification issue, or is it more complex? The Test Series 2 head grades were significantly lower – was it simply due to grade vs. recovery? If some Facilities sulfide material can be heap leached, that likely would result in added value. Tests on sulfide materials should include CN:FA determinations and carbon/sulfur speciation.
- Column leach test gold recoveries from Facilities Oxide core samples were high (86.4% and 83.1%). Silver recoveries were poor.
- Westwood Sulfide core composites were not amenable to agitated cyanidation treatment at P_{80} 19mm or P_{80} 75µm feed sizes. Reagent requirements were generally moderate to high.
- Westwood Sulfide core composites responded reasonably well to rougher flotation. There is potential to improve metallurgical response through optimization of grind size and flotation parameters.
- Flotation response was variable, and different flotation schemes may be required for sulfide materials form different areas.
- Sleeper Waste Dump composites were amenable to agglomeration-heap leaching treatment at P_{80} 19mm crush size. The feeds were, however, low-grade and crushing, agglomerating and heap leaching may not be economic unless waste dumps must be moved to facilitate new commercial production plans at site.
- Facilities Oxide ore represented by these core composites are amenable to heap leaching treatment at a P_{80} 19mm crush size and may be amenable at a coarser crush size.
- Agglomeration pretreatment was required for all column leach test feeds because of high fines/clay content. Cement/lime requirements were reasonably high. NaCN consumptions were high but should be less in commercial production.

- Fines content was high (>20% -106µm material) for all composites used for column leach tests. Agglomeration is required, and conditions should be optimized.
- Bond ball mill work index tests on Westwood samples (assume sulfide) showed the material was hard. Abrasion tests showed it had moderate abrasiveness.
- Bond ball mill work index tests on Facilities sulfide samples showed the material was soft. Abrasion tests showed it had light abrasiveness.

10.3.2 TEST SERIES #2

Conclusions, observations and recommendations for this series of tests are summarized as follows:

- Facilities mixed, Sleeper oxide and West Wood oxide core composite samples were amenable to heap leach cyanidation.
- Facilities, Sleeper, West Wood and South Sleeper sulfide core composite samples were not amenable to heap cyanidation or milling cyanidation processing. Sulfide ores will require oxidation (bio or pressure oxidation) to improve cyanidation recoveries to acceptable levels. Ultrafine grinding should be considered as well.
- Heap leach reagent requirements were moderate to high.
- As mentioned earlier in this section of the report, the recovery variance for Facilities sulfide materials should be investigated.
- In the heap biooxidation phase of this series of tests, the sulfide drill core composites tested (from West Wood, Wood and Facilities areas of the project) were refractory to direct cyanidation treatment, at feed sizes ranging from P_{80} 12.5mm (1/2") to P_{80} 45µm.
- The most likely cause for the low gold recoveries was a locking of gold in sulfide mineral grains.
- All six composites tested responded very well to biooxidation and POX pretreatment for oxidation of contained sulfide minerals, resulting in an improvement in gold recovery by cyanidation treatment.
- Gold recoveries of 90% or greater were obtained by simulated whole ore stirred tank biooxidation, followed by agitated cyanidation, at P_{80} 45µm feed size (3 composites tested).
- Gold recoveries of 86% to 93% were obtained by whole ore POX pretreatment followed by agitated cyanidation, at an 80%-80µm feed size.
- Gold recoveries of 65% to 81% were obtained by simulated heap biooxidation pretreatment, followed by simulated heap leach cyanidation treatment, at P_{80} 12.5mm and P_{80} 6.3mm feed sizes.
- Solution percolation/solution ponding problems were encountered during simulated heap biooxidation pretreatment, particularly at the 6.3mm feed size. Further optimization of heap biooxidation feed size and biooxidation cycle time will be required, if this process is to be considered further. Reagent requirements were high, under conditions not yet optimized.
- Column biooxidation testing should be conducted to optimize biooxidation feed size and cycle time. Special consideration should be given to heap permeability issues. This testing should include load/permeability type testing on biooxidized residues.
- Testing should be conducted to optimize rinsing of the biooxidized residues before cyanidation treatment. This testing should include evaluation of biooxidation solution treatment/neutralization and recycle in the biooxidation circuit and in a rinsing circuit. Proper assessment of acid neutralization costs is needed.

- Column cyanidation testing should be conducted to optimize conditions for heap leach cyanidation of the biooxidized residues. This should include optimization of agglomerating conditions and load/permeability type testing on the leached agglomerates.
- If sufficient higher grade material may be processed, evaluation of milling/cyanidation treatment of a simulated heap biooxidized residue should be considered.
- Optimization of flotation treatment should be considered, including regrind and ultra-fine grinding options.

10.4 SUMMARY STATEMENT FOR PARAMOUNT METALLURGICAL TESTING

The information presented above was received from Paramount and sources as cited. Mr. Woods has reviewed this information and believes it to be materially accurate.

11.0 MINERAL RESOURCE ESTIMATES

11.1 INTRODUCTION

The mineral resource estimates presented herein were completed by RESPEC.

These estimated mineral resources were classified in order of increasing geological and quantitative confidence into Inferred and Indicated categories in accordance with the New Mining Rules. SEC mineral resource definitions are given below:

Mineral resource is a concentration or occurrence of material of economic interest in or on the Earth's crust in such form, grade or quality, and quantity that there are reasonable prospects for economic extraction. A mineral resource is a reasonable estimate of mineralization, taking into account relevant factors such as cut-off grade, likely mining dimensions, location or continuity, that, with the assumed and justifiable technical and economic conditions, is likely to, in whole or in part, become economically extractable. It is not merely an inventory of all mineralization drilled or sampled.

Indicated mineral resource is that part of a mineral resource for which quantity and grade or quality are estimated on the basis of adequate geological evidence and sampling. The level of geological certainty associated with an indicated mineral resource is sufficient to allow a qualified person to apply modifying factors in sufficient detail to support mine planning and evaluation of the economic viability of the deposit. Because an indicated mineral resource has a lower level of confidence than the level of confidence of a measured mineral resource, an indicated mineral resource may only be converted to a probable mineral reserve.

Inferred mineral resource is that part of a mineral resource for which quantity and grade or quality are estimated on the basis of limited geological evidence and sampling. The level of geological uncertainty associated with an inferred mineral resource is too high to apply relevant technical and economic factors likely to influence the prospects of economic extraction in a manner useful for evaluation of economic viability. Because an inferred mineral resource has the lowest level of geological confidence of all mineral resources, which prevents the application of the modifying factors in a manner useful for evaluation of economic viability, an inferred mineral resource may not be considered when assessing the economic viability of a mining project and may not be converted to a mineral reserve.

RESPEC reports resources at cutoffs that are reasonable for deposits of this nature given anticipated mining methods and plant processing costs, while also considering economic conditions, according to the regulatory requirements that a resource exists "*in such form, grade or quality, and quantity that there are reasonable prospects for economic extraction*."

The Sleeper gold and silver mineral resource estimate is reported herein with an effective date of June 30, 2022, based on data derived from drilling performed through 2013. The drill hole database on which this estimate is based was received from Paramount in May of 2022. The database is undergoing an audit, and the last minor changes to collar, survey, and assay data were made on August 09, 2022. The block model is oriented due North, and the blocks are 10 meters by 10 meters by 10 meters.

11.2 DATABASE

Mineral resources were estimated using data generated by Paramount and the historical operators discussed in Section 5 and Section 7. These data were provided to RESPEC by Paramount.

11.2.1 DRILL HOLE DATABASE

The drill hole data are in UTM Zone 11 NAD27 coordinates in US Feet. The database includes information from a total of 4,403 drill holes; a total of 3,994 of these holes contribute assay data that are directly used in the estimation of the project resources.

Paramount provided RESPEC with a project drill hole database prior to the 2021 drilling program. As discussed in Section 9.1, RESPEC audited these historical drill data and made corrections to the database as appropriate. RESPEC then periodically updated the database with the information acquired during Paramount's drilling programs, including gold and silver assay data received directly from the analytical laboratory. Table 11-1 provides a summary of the drill hole database used for modeling and resource estimation.

Table 11-1. Summary of Drilling in the Database for the Sleeper Deposit Resource Estimate

Type of hole	Count	Drilled meter
Core	100	34,001
RC	4,180	593,251
RC/ Core tail	20	7,315
Sonic	92	360
Unknown	11	2,920
Total	4,403	637,847

Table 11-2 presents descriptive statistics of all audited and accepted Sleeper Deposit drill hole analytical and geotechnical data imported into MinePlan 3D© software (v. 13.0). Data from rejected samples have been excluded from the table. There is few trace-element and whole-rock geochemical data.

Table 11-2. Descriptive Statistics of Sample Assays in Sleeper Drill hole Database

	Valid	Median	Mean	Std Dev	CV	Minimum	Maximum	Units
FROM	302,701					0	764	m
-TO-	302,701					0	767	m

Density	2546	2.330	2.329	0.194	0.083	0.060	3.830	g/cm3

11.2.2 TOPOGRAPHY

Paramount provided RESPEC with topographic data for the current project topography, the mined Sleeper pit topography, and the pre-mine topography. RESPEC does not know how the surfaces were generated, however, the extent of the Sleeper pit is in agreement with the blasthole database, and drill hole collar locations correlate well with the current topography. Minor differences between surfaces are apparent, and are attributed to disturbance that occurred during mining, reclamation of the Sleeper pit post mining, and discrepancies that commonly occur between surveys.

11.3 DEPOSIT MODELING RELEVANT TO RESOURCE ESTIMATION

The Sleeper gold-silver deposit is hosted by Tertiary Sleeper Rhyolites and Tertiary Sleeper Basalts. As presently drilled, the core of the known mineralization extends 1,675 meters along strike of the higher-grade mineralization (015° to 020° to the Northeast), approximately 100 meters perpendicular to the strike, and 150 meters in the vertical direction. The deposit is comprised of a core zone characterized by the mined-out Sleeper vein that lies within a broad envelope of lower-grade mineralization. The lower-grade envelope is the primary subject of the resource estimates discussed in following sections of the report.

The low-grade mineralization has extents of approximately 2,000 meters East-West, about 1,250 meters North-South, and up to 600 meters in the vertical direction. Sub-horizontal and sub-vertical veins and breccia bodies of the mid- and high-grade mineralization extend outward into the lower-grade envelope, likely due to stratigraphic and structural controls. The base of the Sleeper vein core zone is sharp, marked by a distinct decrease in the precious-metal grades.

High-grade mineralization (>8 g Au/t) within the core zone related to the Sleeper vein and its stratigraphic and structural extensions has been documented to have been most frequently associated with thin (<5 centimeters), often banded, typically steeply dipping chalcedonic quartz + adularia veins/veinlets. It is important to note that there are examples of high-grade mineralization that have no obvious association with veins, and the presence of veins does not guarantee high grades. In addition, the Sleeper fault has also been hypothesized to be primary controlling feature in the formation of the deposit, and there is evidence of an association between high-angle structural zones and increases in vein density and grades. The distribution of high-grade mineralization distal to the Sleeper vein is somewhat erratic but is locally systematic. For example, the high-grade mineralization at West Wood and the Office areas is related to hydrothermal brecciation.

Stratigraphic control of moderate-grade mineralization is expressed by lenses of generally concordant mineralization that extend out from the margins of higher-grade mineralization along the hanging wall and footwall of the Sleeper vein. The internal layering of the rhyolite and basalt flows are the primary hosts of stratigraphically controlled mineralization.

The Sleeper gold- and silver-bearing hydrothermal fluids are interpreted to have been introduced into the Sleeper Rhyolite and Basalt units along a series of northeast-striking, steeply dipping (primarily to the northwest) structural zones, within the core zone of the deposit. The planar base of this zone and the abrupt change to weakly mineralized and altered rocks below likely reflect the elevation at which boiling of the ascending hydrothermal fluids and deposition of high-grade mineralization was initiated. Outside of the core zone of the Sleeper deposit, deposition of high-grade mineralization is more erratic, which suggests that fluid flow was less focused along poorly defined structural zones. The waning stages of the mineralizing system appear to be manifested as "multi-stage hydrothermal breccias". These primarily clast-supported breccias contain rotated fragments and some mineralized quartz veinlets, and cemented by silica, pyrite, marcasite and adularia and are almost entirely post-mineral.

Post-mineral faulting has resulted in a slight tilting of the Sleeper deposit and its host stratigraphy to the west.

It is within the above-described context of geology that the gold and silver resource modeling was undertaken.

11.4 GEOLOGIC MODELING

Paramount supplied RESPEC with a set of detailed cross-sectional lithological and structural interpretations that cover most of the Sleeper deposit. RESPEC's modeling of gold and silver mineralization was based on these cross-sectional interpretations. The structural interpretations were particularly important to the gold and silver mineral-domain modeling discussed in Section 11.3. RESPEC made minor modifications to Paramount's structural interpretations.

11.5 OXIDATION MODELING

Cross-sectional interpretations of oxidation were used to model zones of oxide, mixed (oxide + sulfide), and sulfide mineralization, and both cross-sections and solids were provided to RESPEC by Paramount. The remaining unmined material is primarily within the mixed and sulfide zones. The most significant portion of remaining oxide zone occurs at shallow depths in the Facility area.

11.6 DENSITY MODELING

A total of 2,546 measurements of bulk density have been conducted by X-Cal and Paramount. All density data were obtained using the water-immersion method on samples of drill core; it is not known if samples were coated as part of the testing. The density data were examined collectively and individually by rock type and oxidation. The combined X-Cal and Paramount Sleeper densities (in g/cm^3) and tonnage factors (in ft^3/ton) grouped by lithology and oxidation is summarized in Table 11-3.

Table 11-3. Sleeper Deposit Applied Densities and Tonnage Factors

Formation	Redox Domain	Number of Samples	Min Density (g/cm^3)	Max Density (g/cm^3)	Density (g/cm^3)	Tonnage Factor (ft^3/ton)
Dumps/Fill	All	0			1.90	16.87
Quaternary Alluvium	All	7	1.76	2.42	1.90	16.87
West Wood Breccia	All	20	2.04	2.56	2.35	13.64

11.7 GOLD AND SILVER MODELING

11.7.1 MINERAL DOMAINS

A mineral domain encompasses a volume of rock that ideally is characterized by a single, natural, grade population of a metal or metals that occurs within a specific geologic environment. In order to define the mineral domains at Sleeper, the natural gold and silver populations were first identified on population-distribution graphs that plot the gold- and silver-grade distributions of all of the drillhole assays, as well as distribution plots using only analyses from core samples. This analysis led to the identification of 3 populations for both gold and silver. Ideally, each of these populations can then be correlated with specific geologic characteristics that are captured in the Project database, which can be used in conjunction with the grade populations to interpret the bounds of each of the gold and silver mineral domains. The approximate grade ranges of the low-grade (domain 100), mid-grade (domain 200), and high-grade (domain 300) domains that were modeled for gold and silver are listed in Table 11-4.

Table 11-4. Approximate Grade Ranges of Gold and Silver Domains

Domain	g Au/ t	g Ag/t
100	0.1 to 1.0	1.80 to 10.0
200	1.0 to 8.0	10.0 to 20.0
300	> 8.0	> 20.0

The gold and silver mineralization was modeled by first interpreting gold and silver mineral domain polygons individually on a set of vertical, 30-meter spaced, north-looking cross-sections that span the extents of the deposit. The mineral domains were interpreted using the gold and silver drill-hole assay data and associated alteration and mineralization codes, as well as sectional lithological and structural interpretations provided by Paramount. This information was used to discern the stratigraphic and structural controls of the mineralization and to model the domains accordingly. Gold was modeled first, and the sectional gold-domain polygons were then used as additional guides for defining the silver domains.

The mid- and high-grade mineralization within the deposit appears to have a discontinuous distribution. To represent this lack of continuity in the model, the boundaries of the mid- and high-grade domains were modeled as a gradational contact within the respective zones. The high-grade gold population (>8.0 g Au/t) is the most readily identifiable grade population in drill core, as it strongly correlates with the presence of thin, often banded, quartz–chalcedony veins and veinlets and/or breccias. Visible gold is sometimes present as well. Drill hole orientations and angles to core axes indicate the high-grade veinlets are most commonly steeply dipping.

The boundary between the low- and mid-grade domains was largely determined by grade. The geologic characteristics of the low- and mid-grade domains were not evident in core and logging. Although the grade change across this domain boundary is generally sharp, it is locally gradational. The grade change across the sub-horizontal base of the mid-grade domain is usually sharp. This basal contact of the mid-grade domain is likely indicative of the elevation at which boiling of the ascending fluids and significant gold deposition initially occurred in the Sleeper hydrothermal system.

The mineralization modeled within the low-grade domain is much less variable than in the two higher-grade domains. This mineralization is distal from the zone of boiling, its related brecciation, and its distribution exhibits strong stratigraphic controls.

The cross-sectional gold and silver mid- and high-grade mineral domains were extruded three dimensionally within each 30-meter sectional window in the North-South orientation and coded to the drill data using tools developed in MinePlan 3D© software. The low-grade domain solid was generated from a geologically constrained indicator interpolation using Leapfrog software. The domain solids within the Quaternary alluvium and the Sleeper dumps were modeled independently and were generated from a geologically constrained indicator interpolation using Leapfrog software within their respective geologic solids.

Examples of cross-sections of the geology, and gold and silver mineral domains in the central portion of the Sleeper deposit are shown in Figure 11.1 to Figure 11-4.

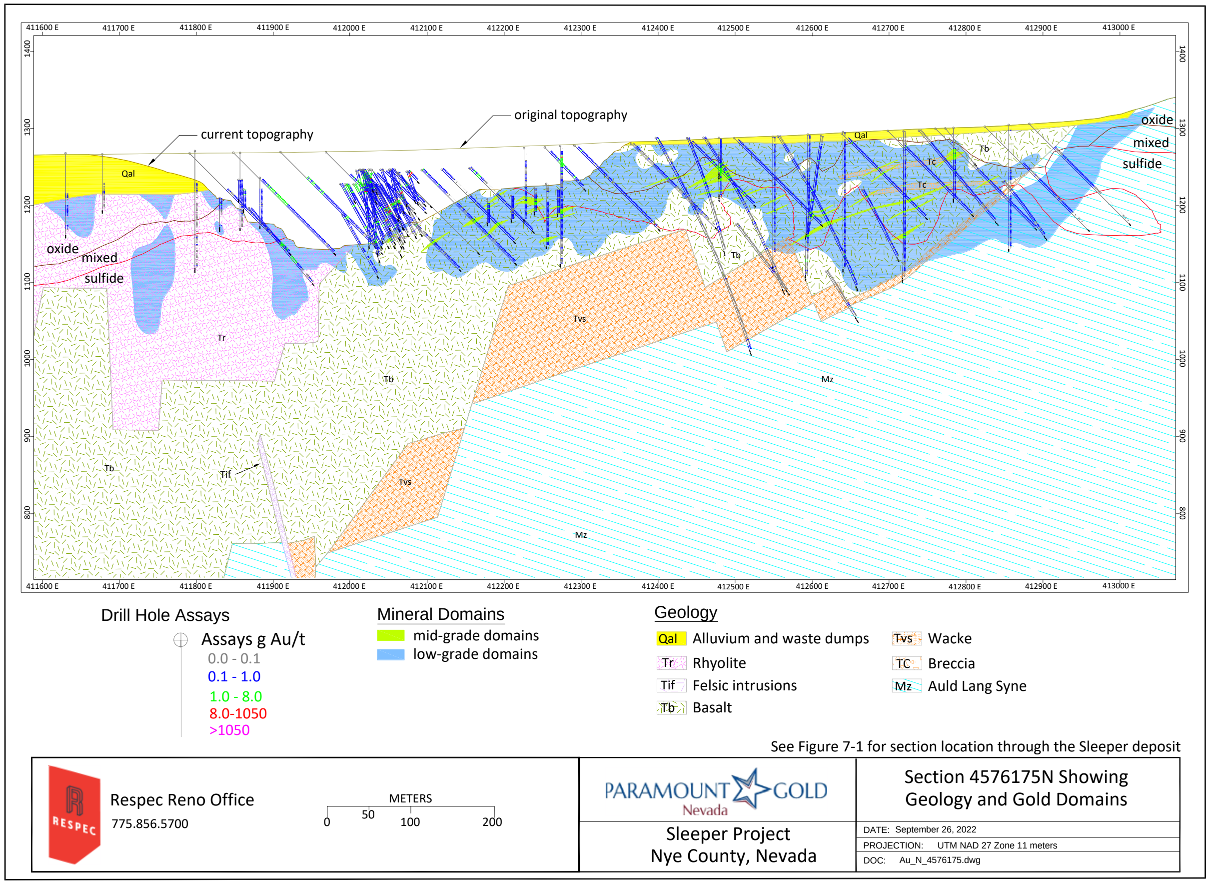

Figure 11-3. East-West Cross-Section 45756175 Showing Gold Domains and Geology.

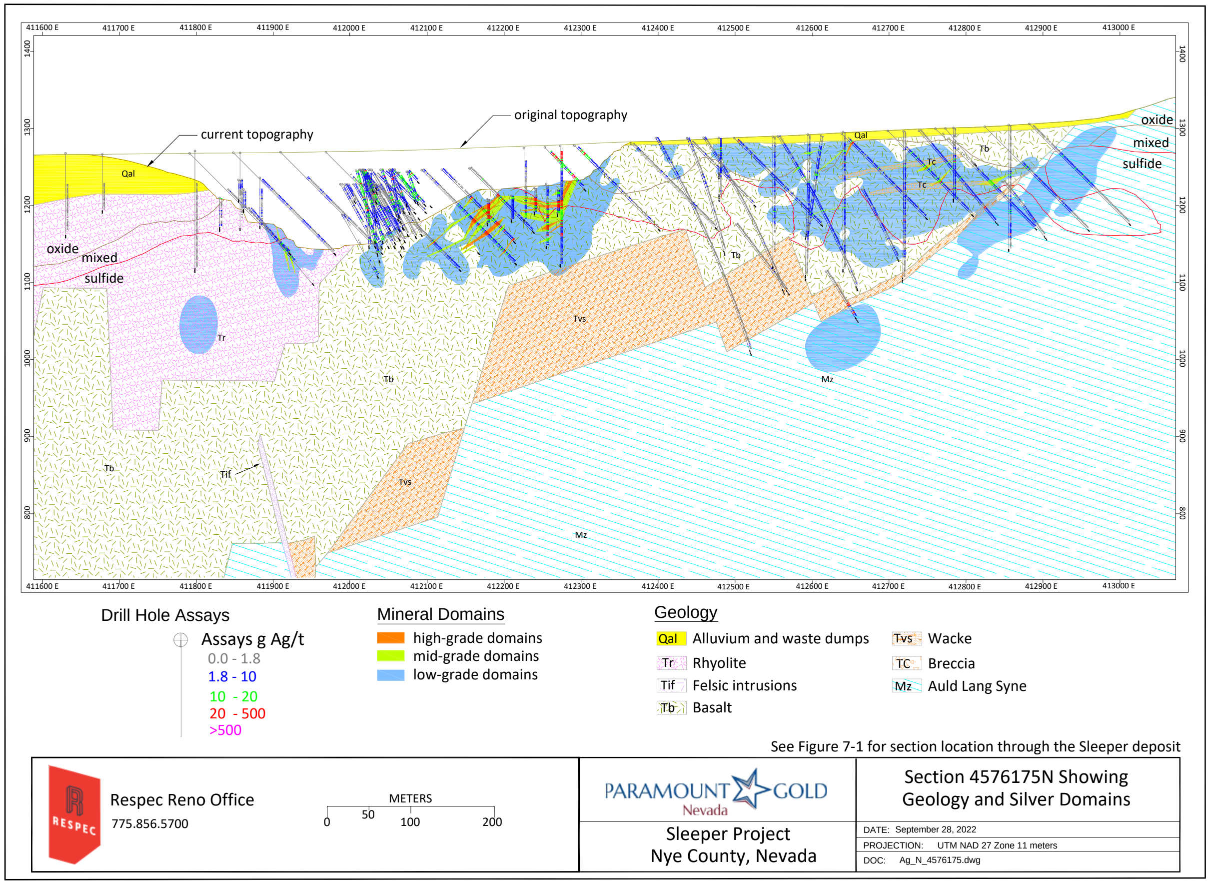

Figure 11-4. East-West Cross-Section 45756175 Showing Silver Domains and Geology.

11.7.2 ASSAY CODING, CAPPING, AND COMPOSITING

Drill hole assays were coded to the gold and silver mineral domains using the mid- and high-grade cross-sectional polygons and the low-grade solid. Assay caps (Table 11-5) were determined by the inspection of population distribution plots of the coded assays by domain, to identify high-grade outliers that might be appropriate for capping. The plots were also evaluated for the possible presence of multiple grade populations within each of the modeled metal domains. Evaluation of descriptive statistics of the coded assays by domain, and visual reviews of the spatial relationships of the possible outliers with respect to potential impacts during grade interpolation, were also considered in the determination of the assay caps.

Table 11-5. Sleeper Gold and Silver Assay Caps by Domain

Domain	Count*	g Au/t	Count*	g Ag/t
Outside	37,138	6	67,011	20
Low-grade	44,548	3	24,106	35
Mid-grade	4,200	N/A	3,044	65
High-grade	246	N/A	1,782	N/A
Alluvium	674	5	163	20
Dumps	432	N/A	140	N/A

* Sample population after excluded samples were removed

Each model block was coded with the volume percentage of each of the five domains for both gold and silver. For model blocks that are not entirely within a combination of the low-, mid- and high-grade domains and the Quaternary alluvium and dump domains, a percentage was calculated for the portions outside modeled domain volumes of the blocks. If a majority of the blocks is outside modeled domains, it was assigned as domain 0 and estimated using assays lying outside of the modeled domains. The domain 0 assays used in this dilutionary estimate were also capped as shown in Table 11-5.

Descriptive statistics of the capped and uncapped coded gold and silver assays are provided in Table 11-6 and Table 11-7, respectively.

The capped assays were composited to 3.05-meters down-hole intervals that respect the mineral domain boundaries. This minimal compositing was chosen to better represent the variability of the Sleeper mineralization in the resource estimation. The odd composite length was chosen to more precisely honor the data that has been converted from the original five-foot drill intervals. Descriptive statistics of Sleeper composites are shown in Table 11-8 and Table 11-9 for gold and silver, respectively.

11.7.3 BLOCK MODEL CODING

The mid- and high-grade mineral domain polygons for each metal were extruded to the mid-plane locations between sections. The resulting solids, in conjunction with low-grade, Quaternary alluvium and dump solids, were used to code into a three-dimensional block model comprised of 10 x 10 x 10 meter blocks (model x, y, z). The bearing is 0°, and the model is not rotated. The block size was chosen in consideration of the open pit mining scenario that would be the likely mining method for the Sleeper deposit. The volume partial percentages of each mineral domain for both gold and silver are stored within each block. The block model was also coded using the digital topographic surfaces described in Section 11.2.2, and the geology and oxidation solids discussed in Section 11.4 and 11.5, respectfully.

The bulk density values discussed in Section11.6 were assigned based on lithology and redox codes as given in Table 11-3 for each block in the model.

Due to the combination of sub-vertical structural controls and sub-horizontal lithological controls, the orientation of modeled mineralization varies throughout the deposit. To properly represent these orientations, nine estimation areas were coded in the block model. Most of the Sleeper deposit mineralization is controlled by the stratigraphic host rocks that dip shallowly at approximately 45° West and is enclosed by estimation area 1. As shown in Table 11-10, the lower-grade gold and silver domains, as well as domain 0, were entirely estimated using search ellipses that reflect these stratigraphic orientations. Estimation areas 2, 3, 4 and 5 encompass steeply dipping mineralization where the dips of the veins and faults range between 60°-75°.

Table 11-10. Sleeper Search-Ellipse Orientations and Maximum Search Distances by Estimation Area

Estimation Area	Search Ellipse Orientation			Maximum Search Distance (ft)			
	Azimuth (degrees)	Dip (degrees)	Rotation (degrees)	Low-Grade	Mid-Grade	High-Grade	Outside Domains
1	0	0	45	150	150	150	50
2	0	0	67.5	150	150	150	50
3	45	0	67.5	150	150	150	50
4	0	0	-67.5	150	150	150	50
5	120	0	67.5	150	150	150	50
6	0	0	45	75	75	75	
7	0	0	45	75	75	75	
Qal	0	0	0	150			
Dumps	0	0	0	150			

Note: Semi-major search distance = major search distance ÷ 1, 1.5 or 2, and the vertical search distance = major search distance ÷ 4

11.7.4 GRADE INTERPOLATION

Gold and silver grades were interpolated using inverse distance ("ID") and nearest-neighbor ("NN") methods. The Mineral Resources reported herein were estimated using inverse distance to the third power ("ID^3") for mid- and high-grade domains and inverse distance to the second power ("ID^2") for low-grade domains. The ID method at the given powers produced results that were judged to represent the geology and drill data most closely. The NN estimation was completed only as a check on the ID interpolations. The parameters applied to the gold and silver estimations at Sleeper are summarized in Table 11-2.

Table 11-11. Sleeper Estimation Parameters

Description	Parameter
Low-Grade Shell Domain	
Samples: minimum/maximum/maximum per hole	1 / 12 / 3
Search anisotropies (ft): major/semimajor/minor (vertical)	1 / 1 / 0.5
Inverse distance power	2
High-grade restrictions (grade in g Au/t, distance in m)	1.6 / 75
High-grade restrictions (grade in g Ag/t, distance in m)	10.5 / 75
Mid-Grade Domain	
Samples: minimum/maximum/maximum per hole	1 / 12 / 3
Search anisotropies (ft): major/semimajor/minor (vertical)	1 / 1 / 0.5
Inverse distance power	3
High-grade restrictions (grade in g Au/t, distance in m)	8.0 / 75
High-grade restrictions (grade in g Ag/t, distance in m)	30 / 75
High-Grade Domain	
Samples: minimum/maximum/maximum per hole	1 / 12 / 4
Search anisotropies (ft): major/semimajor/minor (vertical)	1 / 1 / 0.5
Inverse distance power	3
High-grade restrictions (grade in g Au/t, distance in m)	100.0 / 75
High-grade restrictions (grade in g Ag/t, distance in m)	290 / 75
Outside Modeled Domains	
Samples: minimum/maximum/maximum per hole	2 / 12 / 3
Search anisotropies (ft): major/semimajor/minor (vertical)	1 / 1 / 0.5
Inverse distance power	2
High-grade restrictions (grade in g Au/t, distance in m)	1.1 / 20
High-grade restrictions (grade in g Ag/t, distance in m)	11 / 20
Qal Domain	
Samples: minimum/maximum/maximum per hole	1 / 9 / 3
Search anisotropies (ft): major/semimajor/minor (vertical)	1 / 1 / 0.5
Inverse distance power	3
High-grade restrictions (grade in g Au/t, distance in m)	1.5 / 20
High-grade restrictions (grade in g Ag/t, distance in m)	11 / 20
Dumps Domain	
Samples: minimum/maximum/maximum per hole	1 / 9 / 3
Search anisotropies (ft): major/semimajor/minor (vertical)	1 / 1 / 0.5
Inverse distance power	3
High-grade restrictions (grade in g Au/t, distance in m)	1.1 / 20
High-grade restrictions (grade in g Ag/t, distance in m)	11 / 20

Statistical analyses of coded assays and composites, including coefficients of variation and population-distribution plots, indicate that multiple sample populations were modeled in the various grade domains of both gold and silver. Evaluation of the distribution of grade within the mid- and high-grade domains indicated that the projection of the high grades in the model was excessive and warranted the application of restricted search distances within some domains. The grade and distance of search restrictions were determined using population-distribution plots for each domain. Visual inspection of the higher-grade populations within the model was conducted in a similar manner to capping to determine the potential impact of the higher-grades and the necessary magnitude of the restrictions. Before final search-restriction parameters were derived, multiple interpolation iterations that employed various search-restriction parameters were run to determine the sensitivities of the restrictions on the model.

Estimation passes were performed independently for each of the mineral domains, so that only composites coded to a particular domain were used to estimate grade into blocks coded by that domain. The estimated grades and partial percentages of the mineral domains were used to calculate the weight-averaged gold and silver grades for each block. Grades and percentages outside modeled domains were included in the calculations to produce fully block-diluted grades.

11.8 MINERAL RESOURCES

The Sleeper deposit has the potential to be mined by open pit methods. The Mineral Resources were tabulated to reflect potential open pit mining and heap leach and biooxidation extraction as the primary scenario. To meet the requirement of reasonable prospects for eventual economic extraction, a pit optimization was run using the parameters summarized in Table 11-11.

Table 11-12. Pit Optimization Parameters

Item	Value	Unit
Mining cost	2.00	$/tonne
Heap Leach Processing cost	3.08	$/tonne processed
Biooxidation Processing cost	9.84	$/tonne processed
Process rate	30,000	tonnes-per-day processed
General and Administrative cost	0.46	$/tonne processed
Au price	1,750	$/oz
Ag price	22	$/oz
Au recovery	72.7	percent
Ag recovery	28.2	percent
Royalty	1.5%	NSR

The pit shell created by the optimization was used to constrain the mineral resources, which are reported at a cut-off grade of 0.137 g Au/t for oxide and mixed materials, whereas the sulfide material is reported at a cut-off grade of 0.251 g Au/t. The gold cut-off grade was calculated using the processing, general and administrative costs, gold price, recovery, refining cost, and royalty provided in Table 11-12. The mining cost is not included in the determination of the cut-off grade, as all material in the conceptual pit would potentially be mined as either ore or waste. The reference point at which the mineral resources are defined is therefore at the top rim of the pit, where material equal to or greater than the cut-off grade would be processed.

The metal prices used in the pit optimization and the determination of the gold cut-off grade and gold-equivalency factor are derived roughly from three-year moving-average prices as of August 2022 ($1,750/oz and $22/oz for gold and silver, respectively).

The open pit resource estimates are based on a 30,000 tonnes per day processing rate, with processing assumed to consist of crushing, milling, and first-stage gravity separation followed by carbon-in-leach recovery.

The Sleeper mineral resources are presented in Table 11-13 Mineral resources that are not mineral reserves do not have demonstrated economic viability.

In addition to the mineral resources reported in this summary, there is considerable mineralized material located within the alluvium above and adjacent to the optimized pit. An ID^3 estimation was performed on these mineralized materials and determined to contain approximately 76,000 oz Au within the alluvium. Mining taking place through these mineralized materials to access mineralization in basement rock could potentially contribute to gold and silver production.

Table 11-13. **Sleeper Gold and Silver Mineral Resources**

	Resources			Cut-off Grades (g Au/t)	Metallurgical Recovery
	Amount	Average Grades			
	(tonnes)	g Au/t	g Ag/t		
Inferred mineral resources - Oxide	14,115,000	0.278	1.62	Sleeper Vein Area: 0.137	Au – 85% / Ag – 10%
	18,503,000	0.245	2.49	Facilities Area: 0.137	Au – 79% / Ag – 8%
	1,708,000	0.336	1.05	West Wood Area: 0.137	Au – 72% / Ag – 9%
	3,056,000	0.366	0.97	West Sleeper Area: 0.137	Au – 72% / Ag – 9%
	4,323,000	0.225	3.63	South Sleeper Area: 0.137	Au – 72% / Ag – 9%
Inferred mineral resources - Mixed	53,558,000	0.306	3.80	All Areas: 0.137	Au – 67.5% / Ag – 20%
Inferred mineral resources - Sulfide	105,042,000	0.407	4.15	All Areas: 0.251	Au – 73% / Ag – 43%
Inferred mineral resources- Dumps	15,241,000	0.323	2.09	Mine Dumps: 0.137	Au – 72% / Ag – 42.5%
Inferred mineral resources	215,546,000	0.349	3.53	Inside pit: Variable	Au – 72.9% / Ag – 29.7%

Notes:

- The estimate of mineral resources was done by RESPEC in metric tonnes.
- Mineral Resources comprised all model blocks at a 0.137 g Au/t cut-off for Oxide and Mixed within an optimized pit; 0.251 g Au/t for Sulfide within an optimized pit; and 0.137 g Au/t for dumps.
- The average grades of the Inferred Mineral Resources are comprised of the weighted average of Oxide, Mixed, Sulfide, and dumps mineral resources. Alluvium mineralized materials are not included in the mineral resources.
- Mineral Resources within the optimized pit are block-diluted tabulations. Dumps mineral resources are undiluted tabulations.
- Mineral Resources that are not Mineral Reserves do not have demonstrated economic viability.
- Mineral Resources potentially amenable to open pit mining methods are reported using a gold price of US$1,750/oz, a silver price of US$22/oz, a throughput rate of 30,000 tonnes/day, assumed metallurgical recoveries of 72.7% for Au and 28.2% for Ag, mining costs of US$2.00/tonne mined, heap leach processing costs of US$3.08/tonne processed, bio-leach processing costs of US$9.84/tonne processed general and administrative costs of $0.46/tonne processed. Gold and silver commodity prices were selected based on analysis of the three-year running average at the end of August 2022.
- The effective date of the estimate is June 30, 2022.
- Rounding may result in apparent discrepancies between tonnes, grade, and contained metal content.

Figure 11-5 through Figure 11-8 are cross-sections through the central portion of the Sleeper deposit that show estimated block-model gold and silver grades. These figures correspond to the mineral-domain cross-sections presented in Figure 11-1 to Figure 11-4.

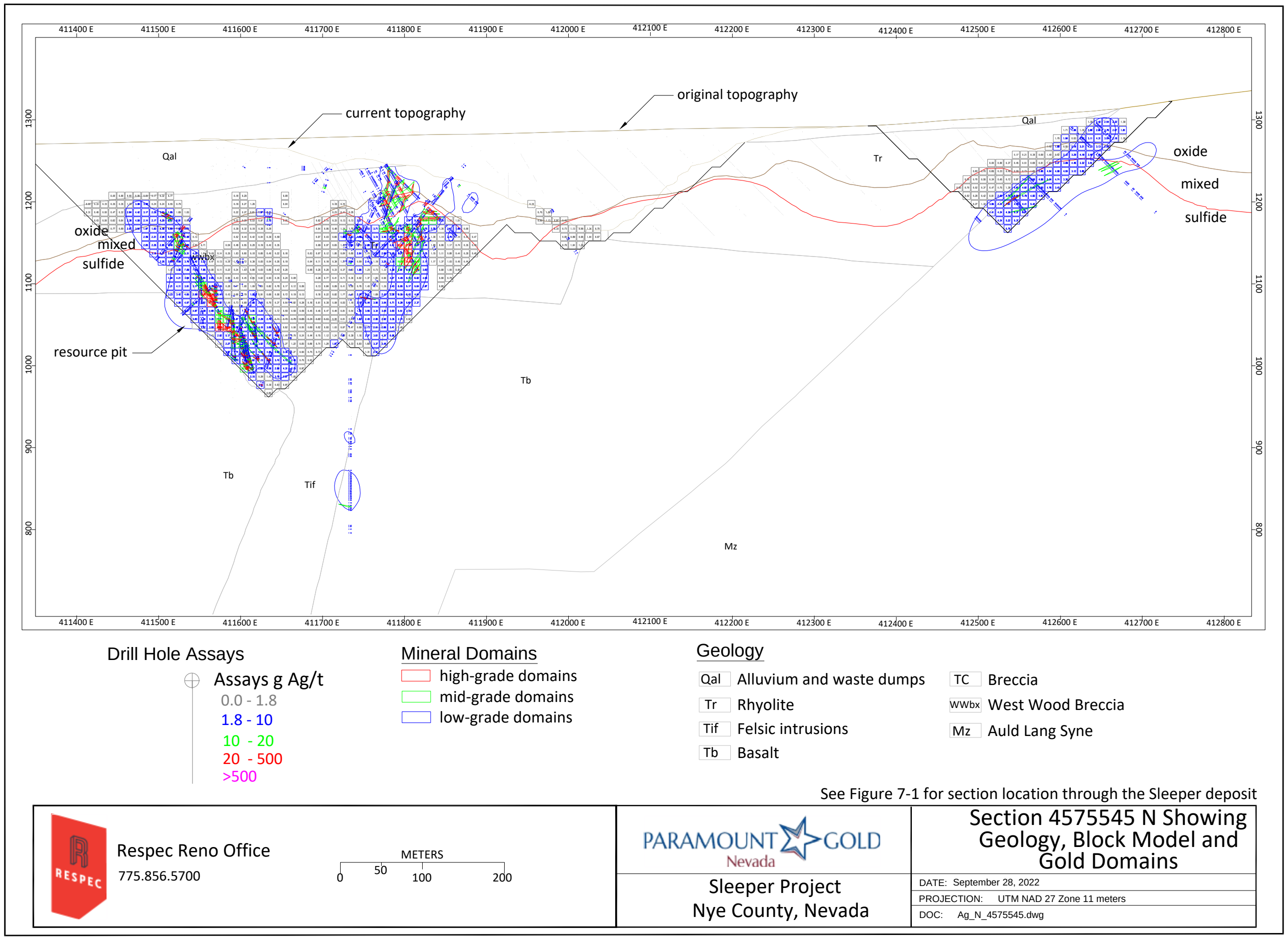

Figure 11-6. East-West Cross-Section **4575545N** Showing Silver Grades in the Block Model

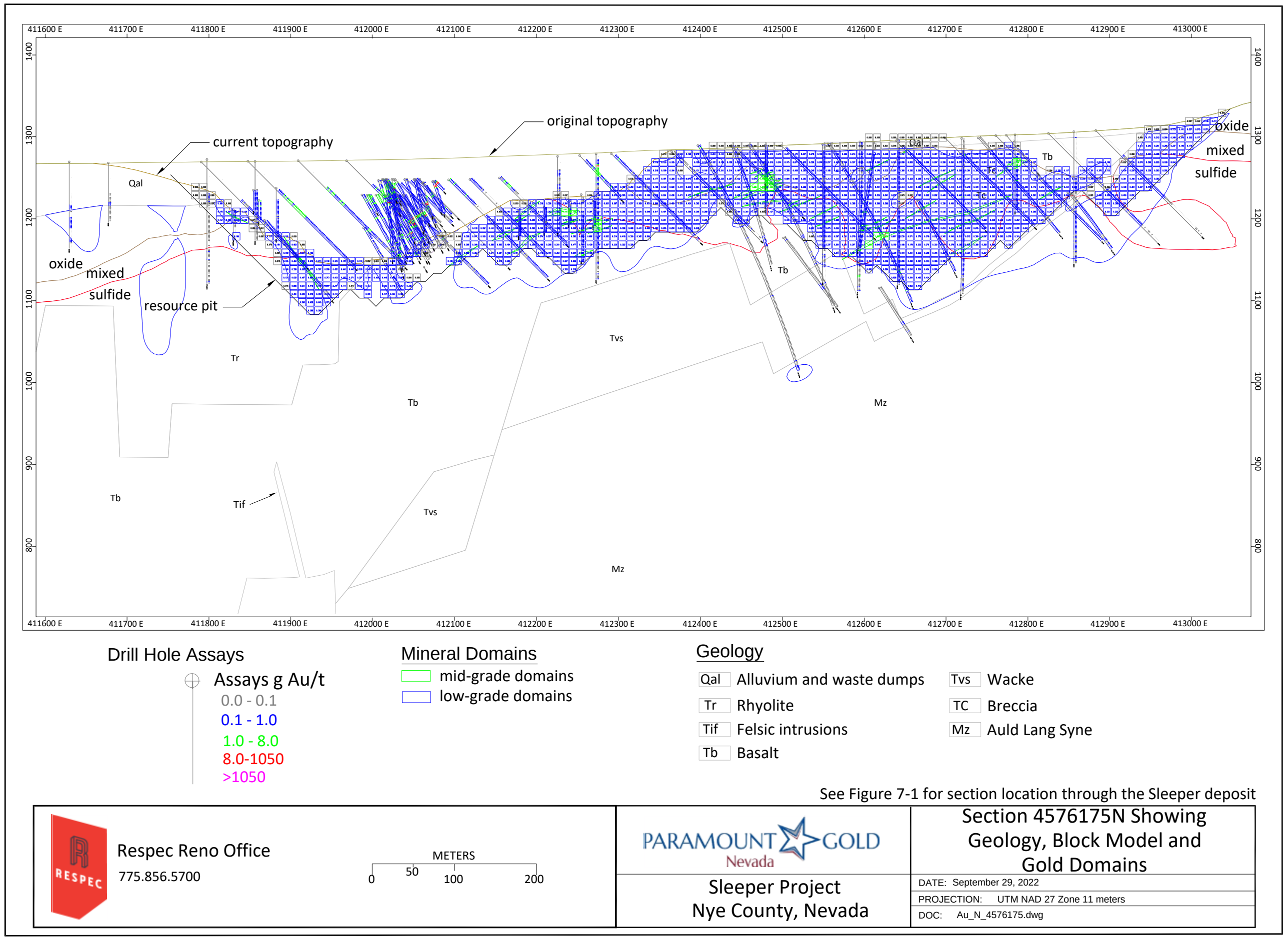

Figure 11-7. East-West Cross-Section **4576175N** Showing Gold Grades in the Block Model

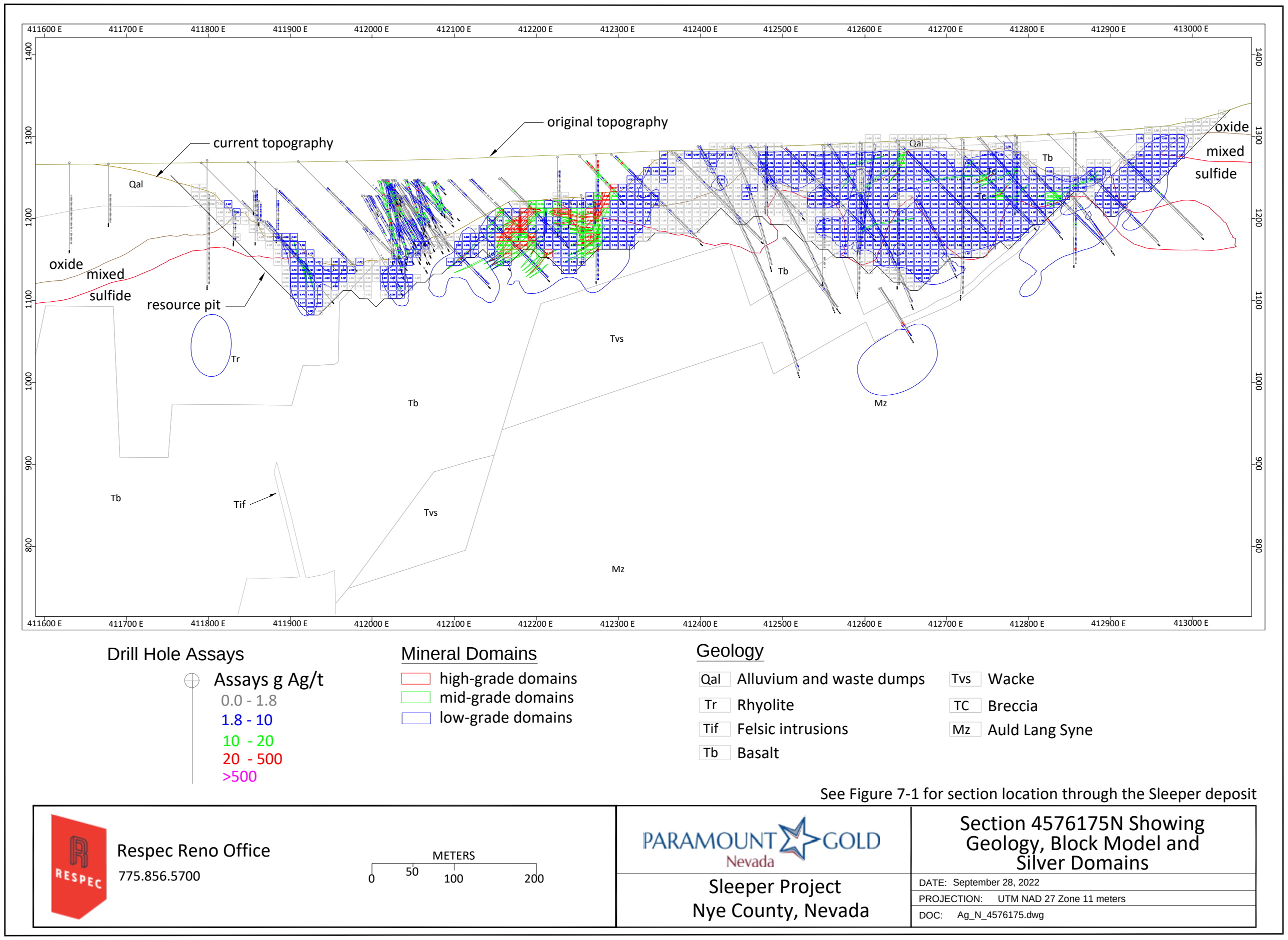

Figure 11-8. East-West Cross-Section **4576175N** Showing Silver Grades in the Block Model

11.8.1 CLASSIFICATION

Due to several factors, the Sleeper resources are classified entirely as Inferred. Uncertainties considered in resource classification include: (i) the preponderance of vertical RC holes drilled and assayed by historical operators; (ii) the poor sample quality due to contamination in some portions of the RC holes; and (iii) the adequacy of the drill hole spacing in the higher-grade core zone of the deposit where variability in the highest-grade gold population is high.

The cross-sectional gold and silver mid- and high-grade mineral domains were extruded three dimensionally within each 30-meter sectional window, in the North-South orientation, and coded to the drill data using tools developed in MinePlan 3D© software. The extruded solids project modeled mineralization uniformly across the 30-meter sectional window, which is not realistic, adds uncertainty to the estimate, and contributes to the exclusive classification as Inferred.

AMAX drilled 3,480 holes that were used in grade estimation for the current mineral resources. The majority of these were vertical. Due to the emerging understanding of the importance of narrow high-grade veins and steeply dipping structural controls to the higher-grade mineralization, subsequent operators, including Paramount, emphasized angled core holes in their drilling programs. A total of 100 core holes, including 39 drilled by Paramount, support the current resource estimates, and enhanced the geological understanding of the Sleeper deposit. The Paramount drilling decreased uncertainties in the resource estimation related to the historical paucity of angled core holes.

In general, there is an inherent risk of down-hole contamination in RC drilling, particularly below the water table. RESPEC identified 14,389 assay intervals with demonstrable down-hole contamination, and 1,291 assay intervals flagged with high-rate of water flow and down-hole contamination of precious-metals values. These samples were excluded from use in the resource estimation. The evaluations were incomplete at the time of the estimate however, so there is potential for identification of additional down-hole contamination. This represents a significant source of uncertainty, since the majority of the historical data is RC drilled below the water table.

The higher-grade zones contain the majority of the metal content in the deposit and are critical to the potential economic viability of a potential mining operation at the Sleeper project. However, the deposit has predominantly been drilled at hole spacings of about 30 meters. Even at this tight drill density, the highest-grade gold mineralization (> 1,050 g Au/t) could not be confidently correlated from drill hole to drill hole. As a result, this mineralization was included within the high-grade domain that contains grades greater than approximately 8.0 g Au/t. The estimation of the highest-grade population within the bimodal high-grade domain was controlled using search restrictions in an attempt to properly represent grade distribution in the model. However, the bimodal character of the domain and the inability to model the highest-grade population increases grade variability and thereby adds uncertainty to the model.

11.9 DISCUSSION OF RESOURCES

RESPEC is not an expert with respect to environmental, permitting, legal, title, taxation, socio-economic, marketing, political, or other relevant factors not discussed in this report. RESPEC is not aware of any issues related to these factors that could materially affect the Mineral Resource estimates as of the effective date of the report.

The block size (10 x 10 x 10 m) of the Sleeper block model was chosen in consideration of potential exploitation by open pit mining and heap leach and biooxidation extraction, and resources were reported within a pit optimized using current economic parameters. However, all modeling processes and inputs that were used to estimate the gold and silver resources, including the mineral domain modeling, grade capping, grade estimation, and density assignment, was completed independent of potential mining methods.

The risks to the reported mineral resources are primarily associated with the high variability and lack of continuity of the highest grades within the deposit and the lower confidence associated with historical datasets. Much of the validation of the historical drilling data, particularly with respect to down-hole contamination, was not completed as of the effective date of the resources. These risk factors contributed to the classification of all resources entirely as Inferred.

The high-grade mineralization demonstrates an erratic distribution, which made correlation of these highest-grade samples from drill hole to drill hole difficult at the current drill spacing. The domain boundaries between the low- and mid-grade domains were largely determined by grade because the geologic characteristics that distinguish those domains were not evident in core or logging. In some cases, relatively high-grade samples were included in lower-grade domains because of the lack of continuity and inability to model the higher grades. There is the possibility that these included higher grades influence more volume than would actually be expected due to the lack of proper domain constraints, however, high-grade search restrictions were applied in attempt to mitigate the risk. The mineralization modeled within the low-grade domain is much less variable than the mid- and high-grade mineralization, which is indicative of more stratigraphic controls on the distribution.

The uncertainty of grade variability and grade location is minimized in an open pit mining scenario. However, properly oriented, closely spaced drilling is needed to fully delineate the mid- and high-grade domain mineralization in the resource models which would increase confidence in the location and extent of the mineralization. Oriented core drilling would also allow for refinement of the geotechnical model for pit slope designs.

The majority of data that was used to estimate the mineral resources in the Sleeper deposit are historical RC drill holes. Much of the drilling data associated with these holes were not able to be verified as of the effective date of the reported resources. There remain uncertainties in the data, for example, in how assays below lower detection limits were recorded in the historical data. There is also an inherent risk associated with RC drilling with respect to down-hole contamination of samples, especially below the water table. A total of 14,389 samples with demonstrated contamination were identified and removed from use in resource estimation; there is significant risk that additional down-hole contamination will be found that could materially affect future mineral resource estimates.

RESPEC believes that any risk factors that would likely influence the prospect of economic extraction could be resolved by further drilling and validation of the historical dataset. Contamination issues below the water table could be avoided by drilling more with core, and closely spaced drilling at an angle would allow for refinement of the mid- and high-grade domain models.

12.0 MINERAL RESERVE ESTIMATES

There are no current mineral reserves at the Sleeper project.

13.0 MINING METHODS

This section is not applicable to the Sleeper project Technical Report Summary.

14.0 PROCESSING AND RECOVERY METHODS

This section is not applicable to the Sleeper project Technical Report Summary.

15.0 INFRASTRUCTURE

This section is not applicable to the Sleeper project Technical Report Summary.

16.0 MARKET STUDIES

17.0 ENVIRONMENTAL STUDIES, PERMITTING, AND PLANS, NEGOTIATIONS, OR AGREEMENTS WITH LOCAL INDIVIDUALS OR GROUPS

This section is not applicable to the Sleeper project Technical Report Summary.

18.0 CAPITAL AND OPERATING COSTS

This section is not applicable to the Sleeper project Technical Report Summary.

19.0 ECONOMIC ANALYSIS

This section is not applicable to the Sleeper project Technical Report Summary.

20.0 ADJACENT PROPERTIES

RESPEC have no information on adjacent properties to report.

21.0 OTHER RELEVANT DATA AND INFORMATION

RESPEC has no other relevant data and information to report necessary to provide a complete and balanced presentation of the value of the Sleeper property.

22.0 INTERPRETATIONS AND CONCLUSIONS

22.1 ADEQUECY OF THE DATA USED IN ESTIMATING THE PROJECT MINERAL RESOURCES

RESPEC has reviewed the Sleeper project data, including information relevant to the project history, geology, and mineralization, and partly verified the drill hole data used in the resource estimation. RESPEC geologists have visited the project site on multiple occasions. Based on this work, it is RESPEC's opinion that the project data are adequate for the modeling and estimation of the current Inferred gold and silver resources as discussed in this report.

22.2 GEOLOGY AND MINERALIZATION

The Sleeper gold-silver deposit is characterized by low-sulfidation epithermal mineralization hosted within a sequence of middle Miocene basalt and rhyolite lavas, domes, and small-volume tuffs. Prior to historical mining, significant zones of mineralization at Sleeper extends for about 2,000 meters along strike, about 1,250 meters of width, and from near the pre-mining surface to depths of more than 600 meters. At least eleven veins with bonanza-type gold grades were mined historically. Within the central core of the deposit, the Sleeper veins generally dip to the west at moderate to high angles, but some secondary hanging-wall offshoots of the principal vein structures dip steeply to the east. The mined-out portion of the deposit included banded quartz/chalcedony veins grading in excess of 8 g Au/t surrounded by a broad envelope of generally much lower-grade mineralization. AMAX mined the Sleeper deposit through open pit mining methods from 1986 to 1996, when a total of approximately 1.66 million ounces of gold and 2.3 million ounces of silver were produced.

During the historical AMAX operation, the Sleeper veins and associated lower-grade envelope were mined through to the down-dip extents of the bonanza-grades. It is these lowermost elevations of the high-grade vein systems that define the base of the historical open pit. Based on detailed reviews of the AMAX blast-hole gold grades and all AMAX and subsequent operators' drilling results, RESPEC believes that the lowermost extents of the high-grade Sleeper veins represent the limit where boiling of ascending hydrothermal fluids had taken place, rather than some structural truncation of the veins. The main vein systems can be traced below the AMAX open pit, but while intermittent high gold grades are present, the overall grades decrease rapidly as down-dip distances from the pit bottoms increase.

The current Sleeper mineral resources are principally comprised of the substantial volumes of the lower-grade mineralization that envelops the Sleeper veins both vertically and laterally. This lower-grade envelope is dominated by stratigraphically controlled, disseminated mineralization, but moderate to high grade mineralization within it includes the down-dip extensions of the historic Sleeper veins as well as other secondary and tertiary structural zones that host hydrothermal breccias of moderate grades. The unmined West Wood occurrence also lies within the low-grade halo mineralization. West Wood is comprised of mid- to high-grade gold mineralization hosted within an easterly dipping, sulfidic breccia of intrusive and volcanic fragments that is related to a felsic dike, and it lies to the south of the AMAX pit limits.

While the drill density is sufficient to potentially define resources of high categories, the current resources are classified entirely as Inferred due to the need for further data verification.

22.3 METALLURGY AND PROCESSING

Six composites responded very well to tests for biooxidation and pressure oxidation ("POX") pretreatment for oxidation of contained sulfide minerals, resulting in an improvement in estimated gold recovery by cyanidation treatment. Gold recoveries of 90% or greater were obtained by simulated stirred tank biooxidation, followed by agitated cyanidation, at P_{80} 45µm feed size. Gold recoveries of 86% to 93% were obtained by POX pretreatment followed by agitated cyanidation at an 80% -80µm feed size. Gold recoveries of 65% to 81% were obtained by simulated heap biooxidation pretreatment, followed by simulated heap-leach cyanidation treatment, at P_{80} 12.5mm and P_{80} 6.3mm feed sizes.

22.4 MINERAL RESOURCES, MINING METHODS, AND MINE PLANNING

Inferred resources, effective June 30, 2022, consist of a total of 215,546,000 tonnes with an average gold grade of 0.349 g Au/t and an average silver grade of 3.53 g Ag/t, for 2,417,000 contained ounces of gold and 24,458,000 contained ounces of silver. The resources are constrained within an optimized pit, reflecting the potential for open pit mining and heap-leach processing of the present Sleeper deposit. The in-pit resources are reported at cutoffs of 0.137 g Au/t for oxide and mixed materials, and 0.251 g Au/t for sulfide material. The cutoff for unoxidized materials reflects the potential for biooxidation prior to leaching. The Sleeper resources are comprised 21% oxidized, 27% mixed, and 52% unoxidized.

22.5 EXPLORATION POTENTIAL

Incremental additions to the current Sleeper resources may be possible with additional infill drilling. West Wood mineralization has a strong association with dikes, and logged dikes are frequently associated with elevated gold values. Mapping and modeling of these intrusions could provide a better understanding of structural control of the West Wood mineralization and could also guide exploration for unidentified West Wood-type mineralization within the main Sleeper resource area.

RESPEC has reviewed Paramount's extensive exploration archive of the Sleeper project, and several target areas with evidence for discovery potential have been identified that have not been adequately tested. Many areas peripheral to the Sleeper gold-silver resource area should be more thoroughly evaluated by excluding shallow drill holes, which on maps used for assessment may give a false negative impression of the actual potential. Many of the holes 100 to 200 meters in depth that lie peripheral to the Sleeper resources failed to encounter bedrock and are thus of limited to no value beyond providing information on the minimum depth to bedrock. The historical grades at Sleeper are high and discovery and development of deposits of similar grades will not necessarily be limited to open pit mining methods.

Future exploration of the Sleeper property must be guided by the extensive historical exploration data archive. Many of the conceptual targets identified to date are hidden beneath post-mineral unconsolidated colluvium and alluvium. Target definition in these areas therefore would need to rely primarily on geophysical evidence. Recommended drilling is proposed in Section 23.1.3.

23.0 RECOMMENDATIONS

RESPEC concludes that the Sleeper project is a project of merit that warrants additional work as summarized in Table 23-1.

Table 23-1 Paramount's Recommended Work Program

Category	Estimated Cost $
Data Compilation and Database Verification	$100,000
Preliminary Economic Assessment	$150,000
Infill RC Drilling (7,600 meters at $132/m)	$1,000,000
Metallurgy including biooxidation test work	$250,000
Pre-Feasibility Study	$2,500,000
Total	$4,000,000

23.1.1 DATABASE COMPILATION AND DATA VALIDATION

Much of the historical drilling information that exists only in hard-copy formats has yet to be compiled and evaluated. It is recommended that special attention be given to compiling and fully evaluating the available historical drilling information, including assay methods and QA/QC procedures and results. The Sleeper database includes multiple generations of data accumulated from several companies. While a 10% validation has been completed with satisfactory results, the remaining 90% of the database is recommended for verification of the data contained. This includes all drill hole information such as collar surveys, down-the-hole surveys, assays, from-to intervals, etc. Once this validation is completed and depending on the issues that need to be resolved, there may be opportunities to upgrade the classification of portions of the estimated mineral resources at Sleeper. The estimated cost is approximately $100,000.

23.1.2 RESOURCE UPDATE AND PRELIMINARY ECONOMIC ANALYSIS

Following completion of the database audit, an updated estimate of the mineral resources is recommended. If the infill drilling allows for sufficient re-classification of the resources to Indicated and/or Measured status, a preliminary economic assessment ("PEA") is recommended to assess the preliminary project economics. The estimated cost is approximately $150,000.

23.1.3 INFILL DRILLING PROGRAM

If the results of the recommended resource update and recommended PEA are favorable, an infill drill program of approximately 7,600 meters of drilling is recommended. The drilling is proposed to be completed by RC methods with an estimated cost of about $132 per meter. However, RESPEC recommends that core drilling be substituted for a portion of the RC drilling due to the emerging understanding of the importance of narrow high-grade veins and steeply dipping structural controls to the remaining higher grade mineralization, and to avoid the demonstrated down-hole contamination that has occurred below the water table. Core drilling would also provide opportunities to collect information regarding geotechnical data, hydrology, metallurgical testing, and validate historical RC drilling. Increased drill density is required in some areas to provide confidence needed to potentially upgrade Inferred resources to Measured and Indicated classifications. The estimated cost is approximately $1,000,000.

23.1.4 METALLURGICAL TEST WORK

If the results of the recommended resource update and recommended PEA are favorable, a metallurgical test program should be carried out at a level that would support a pre-feasibility study ("PFS") and using samples that are representative of the deposit. Some of these samples should be obtained from the "West Wood" portion of the Sleeper deposit area. Others should be obtained from the "Facilities" area. While many detailed metallurgical tests have already been completed, more work is required for the determination of optimum biooxidation recovery methods.

Column biooxidation testing should be conducted to optimize biooxidation feed size and cycle time. Special consideration should be given to heap permeability issues. This testing should include load/permeability type testing on biooxidized residues. Testing should be conducted to optimize rinsing of the biooxidized residues before cyanidation treatment. This testing should include evaluation of biooxidation solution treatment/neutralization and recycle in the biooxidation circuit and in a rinsing circuit. Proper assessment of acid neutralization costs is needed. Column cyanidation testing should be conducted to optimize conditions for heap leach cyanidation of the biooxidized residues. This should include optimization of agglomerating conditions and load/permeability type testing on the leached agglomerates. If sufficient higher-grade material may be processed, evaluation of milling/cyanidation treatment of a simulated heap biooxidized residue should be considered. Optimization of flotation treatment should be considered, including regrind and ultra-fine grinding options.

The estimated cost is approximately $250,000.

23.1.5 PRE-FEASIBILITY STUDY

If the results of the recommended PEA are favorable, a PFS is recommended. The required elements of a PFS will be determined based upon the results of the PEA. A budget of $2,500,000 for the PFS is proposed here.

25.0 RELIANCE ON INFORMATION PROVIDED BY THE REGISTRANT

The following categories of information have been provided to RESPEC by Paramount:

- Electronic copies of documents, reports, maps, tables, and 3D topographic shapefiles that Paramount acquired from historical operators of the Sleeper property concerning concession boundaries, property history, geology, and historical drilling and sampling;
- Electronic copies of documents, reports, maps, tables, and 3D geologic shapefiles provided by Paramount with the results of drilling and sampling carried out by Paramount through the effective date of this report; 3D topographic shapefiles and
- Electronic copies of maps, photographs, drilling data tables, and laboratory assay reports and certificates from Paramount's 2010 – 2013 drilling.

RESPEC has taken all appropriate steps, in their professional judgment, to ensure that the work, information, or advice from the above noted information and companies is sound. The uncertainties and lack of verification of the data have been disclosed in Section 5.2, Section 7.4, Section 7.5, Section 8.1, Section 8.2, and Section 8.3.

RESPEC has fully relied on Mr. Glen Van Treek, President of Paramount, to provide complete information concerning the pertinent legal status of Paramount and its affiliates, as well as current legal title, material terms of all agreements, and material environmental and permitting information that pertains to the Sleeper project. RESPEC has therefore relied fully upon information and opinions provided by Paramount with regards to the land tenure summarized in Section 3.2, Section 3.3, Section 3.4, Section 3.5 and Appendix A. RESPEC has no reason to believe that any material facts have been withheld or misstated and this is why RESPEC considers it reasonable to rely upon the registrant for the information summarized in Section 3 of this report.
